Finsen Light Therapy in Lupus Vulgaris.—Lomholt reviews the evolution, construction and operation of Finsen apparatus for lupus vulgaris and the successful results achieved either by local irradiation or by supplementary light baths of the body. Of 187 patients, 175 (96.7 per cent) were cured. Reexamination, after a period of years, of 350 patients, representing a section of the country whose past history was one of serious and neglected cases, showed 76.5 per cent healed and 16 per cent with smaller and 7.5 per cent with larger infectious traces. Two thirds of all patients were women. The therapy consists of from four to six series of treatments (direct current, 40 ampere lamp intensity) lasting from twenty to thirty minutes each and extending from two to three weeks and leaves soft, smooth scars with a minimum of disfigurement. Patients report for periodic reexaminations. The author points out that a parallelism was found statistically between the incidence of pulmonary tuberculosis and lupus vulgaris in different districts of the country. A bacteriologic test showed the presence of bovine tuberculosis in 45 per cent of 110 cases in which reaction was obtained, though lupus, contrary to the general belief, is not predominantly a rural disease and is found in countries, such as Norway and Finland, in which bovine tuberculosis is practically unknown.

Atherosclerosis.—Grotel and his co-workers studied 485 patients with a clinical diagnosis of atherosclerosis and 105 control patients. In 134 cases of the group presenting atherosclerosis a postmortem examination was made. In the present study only the cases with a postmortem (134) are included. Histories and microscopic studies were carried out according to a definite scheme. An attempt was made to correlate the two. The effect of alcohol, nicotine, psychic factors and infection was investigated. Microscopic studies failed to establish any important role of alcohol in the development of atherosclerosis. Attention is called to the frequent occurrence of atherosclerosis among Mohammedan peoples, almost none of whom use alcoholic drinks. A study of thirty heavy smokers and twenty persons who did not smoke demonstrated the existence of a definite

parallelism between smoking and the degree of atherosclerosis, especially with regard to the coronary arteries. There were three times as many smokers with coronary atherosclerosis as nonsmokers (75 per cent and 25 per cent). Likewise among patients exhibiting a more severe degree of atherosclerosis of the brain vessels there were 65.5 per cent of smokers and 34.5 per cent of nonsmokers. With regard to the influence of the psychic sphere, the authors found that among patients exhibiting a high degree of aortic sclerosis 40 per cent had a history of psychic trauma as compared with 30 per cent who did not have such a history. Intensive work as a factor in definite aortic sclerosis was noted one and one half times more frequently than in a group with a mild degree of atherosclerosis. Psychic trauma was absent in 32.5 per cent of cases of mild degrees of coronary atherosclerosis, whereas psychic trauma was absent in only 17.3 per cent with marked coronary atherosclerosis. As the degree of coronary atherosclerosis increased, so did the incidence of psychic trauma. The shocking or sudden psychic trauma and intensive intellectual labor were found predominantly in the group with grave coronary atherosclerosis, whereas chronic protracted trauma was more frequent in the group of atherosclerosis of brain vessels. Infectious diseases did not seem to influence the incidence of atherosclerotic changes. A slight predominance existed only in the case of rheumatic infection and pneumonia. With regard to the role of nutrition, the material was divided into three groups: (1) the group with normal nutrition, (2) the group with prolonged, excessive nutrition, particularly with regard to animal proteins and cholesterol-containing substances and (3) the group with a history of prolonged periods of insufficient food intake, particularly of animal proteins and cholesterol-containing substances. In a group exhibiting a mild degree of atherosclerosis, the greatest incidence belonged to the group with insufficient nutrition. As the degree of atherosclerosis increased, the predominance was taken by the group with normal or excessive nutrition. The same relation was noted with regard to coronary atherosclerosis. The greater the degree of coronary involvement, the less is the percentage of patients with insufficient nourishment and the greater the percentage with normal or excessive nourishment. The authors emphasize the dependence of the degree of atherosclerosis of the aorta and of the coronary vessels on excessive use of cholesterol-containing substances. The following conclusions were drawn: 1. Chronic alcoholic intoxication apparently has a secondary role in the etiology of atherosclerosis. 2. A chronic nicotine intoxication assists in the development of atherosclerosis in general and of coronary atherosclerosis in particular. 3. The significance of excessive nourishment and particularly of excessive intake of animal proteins and cholesterol-containing foods is definite. 4. Psychic trauma plays an important part in the development of coronary atherosclerosis. This is true of sudden psychic trauma as well as of long continued overwork on the part of the psychic sphere (intensive intellectual labor). 5. The role of infections in the etiology and pathogenesis of atherosclerosis has not been demonstrated.

Dietetic, Ammonium Chloride and Digitalis Therapy of Cardiac Decompensation.—According to Gruzin the effect of rapid dehydration of a dropsical patient by means of powerful diuretics such as merbaphen, salyrgan and mercurosol is not always a favorable one. Rapid dehydration weakens the organism. The effect of mercurial preparations on the kidneys is not a harmless one and the excellent diuretic effect is almost always transient and is not infrequently followed by an increase in the edematous state. The author proposed in 1936 a combined therapeutic method which can be modified, depending on the needs in the individual case. The essence of the treatment consists in giving a cardiac patient in a state of decompensation

a calorically adequate diuretic diet and ammonium chloride for four days. The diet consists of milk, whey, baked apples, cream, sugar, butter, baked potatoes, and dextrose intravenously. The albumin content of the twenty-four hour ration amounts to 84 Gm., of fats to 41 Gm. and of carbohydrates to 191 Gm. The caloric value amounts to 1,515. Most of the ingredients in this diet possess a diuretic effect. This ration is divided into five or six portions. Addition of ammonium chloride increased diuresis. Ammonium chloride was found not to be injurious to the kidneys, even in the presence of a chronic nephritis. Studies of the alkali reserve of the blood after protracted administration of ammonium chloride demonstrated an increase in the alkali reserve of the blood and a lowered ammonia in the urine. The author's experience with over 1,000 patients suggests the superiority of the gradual method of dehydration by means of his combined method over the administration of mercurials. In cases accompanied by tachycardia and arrhythmia the author added to the foregoing 0.1 Gm. of digitalis three times daily.

Carcinoma of Breast and Ovarian Function.—According to the Heibergs there is disagreement about the nature of the relationship between the ovarian function and the development of carcinoma of the breast. They cite statistics on the incidence of mammary carcinoma in married and unmarried women, among others an investigation into the mortality from mammary carcinoma undertaken by the League of Nations in 1926. This report indicated that the death rate was higher in unmarried than in married women. Herrel demonstrated in 1937 that double oophorectomy exerts a protective influence against mammary carcinoma. In the same year Olck showed that the menopause occurs later in patients with mammary carcinoma than in other women. These three different clinical factors, high incidence in unmarried women and in those with a late menopause and the seemingly protective influence of castration, suggest that mammary cancer occurs most frequently in those in whom the menstrual cycles have been most frequent. The authors' inquiry into the proportion of unmarried to married women among those who died from mammary carcinoma in Denmark during the years 1931-1937 likewise indicates a higher mortality among unmarried than among married women. Clinical notes on 1,200 cases of mammary carcinoma from different hospitals in Copenhagen revealed a greater number of unmarried than of married women, compared with the relative proportions in the corresponding age groups of the general population. The menopause was found to occur later in women with mammary carcinoma, but it was not possible to establish a connection between previous gynecologic or endocrine disease and the development of carcinoma of the breast. The authors consider it possible that the predominance of mammary cancer in unmarried women may be due to the more frequent development of one particular type of carcinoma. They hope that microscopic studies will help in differentiating this and other types of carcinomas.

Bone Marrow in Regeneration of Bone.—Levander calls attention to a disagreement as to the role assumed by the bone marrow in the production of callus. He carried out two series of experiments in rabbits with grafting of bone marrow into soft tissues. All grafting was autoplasmic and made into the subcutaneous tissue. Twelve full grown rabbits were used in the first series of experiments. The period of observation varied from fourteen to fifty-eight days. In five cases bone formation was obtained. In the second series, carried out with the view of studying the histogenesis of the regenerated bone, young animals were used, the period of observation being from two to

eleven days. Morphologic analysis of the tissue reactions in this series showed that the grafted bone marrow cells had died. The new bone apparently arises from the mesenchymal tissue formed around the graft. It is the author's opinion that there are no preexisting osteoblasts in the bone marrow. Instead, the bone marrow stimulates bone formation through some inherent substance possessing the power of influencing the nonspecific mesenchymal tissue to form bone.

- Kala-Azar (Visceral Leishmaniasis). A. H. Brinchmann.—p. 297.

Benign Gastric Tumors.—According to Myhre, benign gastric tumors, which he classifies as epithelial and not epithelial, are relatively frequent. The epithelial tumors (adenomas and adenopapillomas) occur far more often than the not epithelial (myomas and numerous other forms). A few cases of aberrant pancreatic remnants in the stomach wall have been reported and are classified as not epithelial tumors. The epithelial tumors may be solitary or few. In some cases they line the stomach wall. Most of them enter under the concept of a polyp, where a number of the not epithelial forms also belong because of their macroscopic appearance. The polyp form is ascribed to the action of peristalsis on the tumor. Epithelial tumors are often accompanied by gastritis and anacidity and not infrequently undergo malignant degeneration. Other important symptoms of benign gastric tumors are hemorrhages, constriction and invagination of the stomach. Many cases are latent or partly so and are accidental discoveries at necropsy. Diagnosis must depend on x-ray examination, made with especially careful technic, and on gastroscopy. Some of the small tumors, also larger angiomas, when very soft, can be established only by gastroscopy. Four cases are described in which gastroscopy was done.

5:319-370 (Feb. 24) 1940

- *Functional Aortic Insufficiency. H. A. Salvesen.—p. 320.

Functional Aortic Insufficiency.—Salvesen believes that functional aortic insufficiency in hypertonic nephritis is far more frequent than was formerly supposed. There was a diastolic regurgitation murmur over the heart, usually over the apex or near it, in twelve (18.75 per cent) of the sixty-four fatal cases of azotemic uremia treated from 1925 to 1939. The valves were normal, and, while there was marked hypertrophy of the heart, no distention of the aorta or of the ostium aorta was demonstrable, and a relative insufficiency due to distension seems improbable. There were no peripheral manifestations of aortic insufficiency. A certain physiologic insufficiency is assumed to exist. The regurgitation murmur is interpreted as a functional insufficiency (pathologic increase of the physiologic insufficiency) dependent on the high pressure (pressure insufficiency).

Sternal Punctate in Idiopathic Thrombopenic Purpura.—Holten and Munkholm examined the bone marrow of seven patients with idiopathic thrombopenic purpura, in two cases half a year and four years respectively after splenectomy, in one case shortly before and shortly after splenectomy and in four cases before splenectomy. No difference in the sternal punctate of the patients operated on and those not operated on could be demonstrated, and there were on the whole no deviations from the normal which could not be explained as lively regeneration due to the bleeding. No certain changes in the megakaryocytes were established.

BETTER HEALTH FOR AMERICA

PRESIDENT'S ADDRESS

NATHAN B. VAN ETEN, M.D.
NEW YORK

Better health for America is the objective of the organized medical profession, which I have this year the honor to represent. Organized medicine is devoted to the public service and always has been in America since the first hospital was organized 188 years ago in Philadelphia for medical service to the sick poor. Today 116,500 of the physicians of the United States provide service to people of all social economic levels. These servants of the sick are on call twenty-four hours of every day.

Although the census taker insisted on recording me as working forty hours a week, there have been few days in the last fifty years in which I have not spent more than twelve hours in the service of people who asked for it. Beginning as a general practitioner with surgical training and a generous exposure to medical education, here and abroad—a fortuitous circumstance through the medium of an epidemic of typhoid fever—the demands of other infectious diseases and many calls to obstetric service gradually shaped my course into the field of internal medicine. This very ordinary experience has been shared by thousands of physicians who have been making available this type of public service with considerable satisfaction to the American people.

Organized medicine has been trying for the last ninety-four years to inspire all its members, who represent 85 per cent of the active practitioners in the United States, with high ideals and with a sense of their responsibility for good public service. It has often been obliged to censor the conduct of members who have been involved in quackery or questionable commercialism. It has often been obliged to take the field against unlicensed people who have mercilessly exploited the confidence of sick people who were suffering from incurable cancers or other fatal conditions. Some of these criminals have fought back and are still evading the law of the land, but in every instance the efforts of organized medicine on behalf of the people have been justified.

HEALTH EDUCATION OF THE PUBLIC

There would seem, however, to be no end to the necessity for organized medicine to exercise its educative crusades, because there seems to be no prospect that human credulity can be relieved from its beliefs in miraculous performances of conscienceless swindlers.

Ignorance is responsible for many tragedies. Organized medicine will not fulfil its functions as the protector and promoter of the public health unless it continues with greater enthusiasm and greater determination to educate the people in every phase of healthful living and without reservation warns them against the dangers of untreated communicable diseases. Plain talk in unpleasant language must not be shirked if necessary to shock ignorance into intelligence.

We must not take negative positions at a time like this when all sorts of wild theorists are shouting into the public ear. The people seem to be eager for health education and we must give it to them honestly and freely if we really want America to be a better and happier place in which to live.

EDUCATION OF THE PHYSICIAN

The practical education of the physician seems to take on new significance with the necessity for integrating physicians and laymen in informative campaigns to win support for the medical profession. Only in this way can we succeed in efforts to maintain the quality of medical service in the face of organized attacks by those who would substitute mass medicine for our present system.

I question the practicalities of the present pursuit of the degree of Doctor of Medicine, which follows a course of education which is too long and too short; a course which is more heavily loaded than is required for any other professional degree; too long to permit the student to enter practical life in his best years and too short to feed him the special fundamental knowledge he should possess before he steps into his public service.

Eight years of required college work brings the average student to 26 or 27 years of age before he leaves school. Then he must have two years of hospital work to learn the practical application of some of the facts he has learned. He will then be 29 or 30 years old before he may be permitted to earn his living through professional work. I do not believe that four years of medicine is too long or long enough, but I believe that some procedure should be evolved to bring the physician earlier into practice. Possibly he might be well prepared for his peculiar life by giving him six years of scientific and medical education, omitting all frills and specialty teaching and concentrating on practical general medicine, and minor surgery and traumatic and obstetrics, in order to give him the best preparation for the average care of the average patient.

Internships are most valuable opportunities to learn practical medicine. The patients are human beings who represent the average of clinical experience. If the intern is wise he will think of them as prototypes of the patients he hopes to have; he will study each one as an individual; he will try to learn something of his

biologic inheritance and his social experience; he will not classify him as a case of this or that disease but as a person suffering from a disease; he will not treat a disease but he will treat the patient. If he will always do this he will come to know people, and such knowledge will attract people to him.

Concentration of medical education into six years of scientific study will, of course, be criticized by the advocates of broad culture, which they claim is necessary to the joy of living and the understanding of human problems. I believe, however, that giving the physician as clear a vision of the physiology of life as possible would be the best equipment for him to apply as a scientific approach to the treatment of sick people, who will in their turn educate him in the real values of public service.

If the physician has a flexible intelligence he will, no doubt, follow an inclination toward some satisfactory hobby. A surprising number of physicians have found delight in the pursuit of the charms of music; many have recently exposed to public view their accomplishments in the fields of painting and sculpture; many have found leisure for the refreshment of outdoor sports and the pursuit of studies in natural history.

Culture will bless the physician if he desires it, but his chief satisfactions will come from his efforts to help people who are suffering from the incapacities of sickness.

THE SPECIALTIES

All of modern medicine has been developed within the last fifty years, so rapidly that it has been difficult if not impossible to include more than smatterings of the teaching of specialties in courses supposed to cover the entire field of medicine and surgery. New ideas have dazzled imagination with the brilliant prospects of solution of age old problems of diagnosis and cure. Students have been lured into following gleaming stars before they have firmly planted their own feet on firm foundations.

Probably inspired by romantic admiration of brilliant individuals, many interns enter hospitals with definite ideas of becoming specialists. A good many young physicians who take short cuts into specialism immediately after leaving their internships are lured by the dream of quick financial reward. They do not know that very few specialists have attained material success. They do not realize that the specialist has experienced greater difficulty in times of depression than the general practitioner.

It is claimed that the competent general practitioner can give satisfactory care to 85 per cent of all sick people. Competent general practitioners who have adapted themselves to the financial competence of their patients and have asked modest fees have had plenty of work during the last decade, while specialists have been idle because people were unable to pay them and because they were known to have limited themselves to very narrow fields.

Specialism has been overdone to the great injury of the specialist. Many unqualified practitioners have called themselves experts. The special societies have tried to raise the quality of specialization by setting up examining boards and are apparently meeting with success. They intend that only the really qualified may be permitted to identify themselves with special titles. These are doctor's doctors to whom difficult problems should be referred, but there are too many of them. I myself know expert men who are seriously embarrassed

and are very unhappy because they do not know how to step down from their conspicuous places. It is just as true now as it always has been that specialists are greatly helped by a knowledge of the whole man gained through years of general practice. It is axiomatic that a young doctor cannot begin at the top and therefore his education must be devised to prepare him to understand the average clinical problems which are presented by average patients.

DEMANDS CAUSED BY MODERN LIVING

Life has been so externalized by scientific disclosures of one objective revelation after another that the results have been accepted without inquiry as basic facts from which to step steadily forward from one civilizing accomplishment to another. Electric light and power, telephones, radios, modern plumbing, airplanes, automobiles, all are accepted as necessities of life. Everybody must use them to live contentedly. All must be items in the daily budget. Cheap moving picture entertainments are considered necessary satisfactions; all divisors of time and the vitality and the cost of living; all changing man's point of view; all educating him; all prodding him to sleepless activity and to superficiality. Man is too busy to think beyond the current moment; too busy to know his own children who are too busy to enjoy family life; too busy to remember the abiding precepts of religion; too busy to pass those satisfactions along to his children; all pursuing elusive pleasures of work or play which may lead them into early neuroses which make them difficult or impossible to live with.

Because modern speed has eliminated the horse and buggy doctor, his successor is confronted with the prospect of more difficult and newer educational demands.

Education of every physician must continue throughout his life. Many of the constituent bodies of the American Medical Association now carry on this work, in some counties enlisting the interest of more than 90 per cent of all resident physicians. Not only the city physician who has many opportunities for stimulating study but the most remote country physician is eagerly receptive of these efforts to bring to him the most modern ideas and technics of clinical medicine.

I have recently seen the graphic charts of postgraduate education in clinical medicine in Tennessee, where the response of physicians from remote mountainous districts as well as from the town was most remarkable. In many instances physicians brought their immediate clinical problems to the classes for study and consultation.

There are of course physicians who rarely study, who practice the kind of medicine they started with when they left the medical school. I believe this lazy attitude is more common in large cities where physicians have easily available institutional help which they may call on when they get beyond their depth than among country physicians, whose very existence depends on self reliance.

COUNTRY PRACTICE

Only competent physicians can succeed in country practice—ignorance and chicanery are quickly detected in places where the physician is conspicuous because he stands alone. The only safe place for incompetents is in cities, where they may hide in the crowds.

If young physicians who are fortified by strong characters, good education and real ability will seek small

towns or country fields, they will find plenty to do for real people and the satisfaction of living, which are denied them by the lack of all kinds of elbow room in big cities.

A good quality of medical service is needed in every part of our country. The United States presents every physical characteristic, mountains and valleys and arid lands and fertile lands, sea coasts, rivers, harbors, lakes, mines, oil fields, great crowded cities, small towns and farms, hot and cold climates, good and poor transportation, good and bad roads—all creating and modifying medical problems.

HOSPITALS

The people who live in this country represent every race, every religion and speak every tongue, but they are all human beings anatomically and physiologically the same, with the same necessities for physical care. All of them need available medical care for all ordinary illnesses and accessible places where they may be hospitalized for conditions which cannot be treated at home.

The President of the United States thought of such facilities in his new proposal to build small hospitals where they are needed. They do not need to be elaborate buildings, expensively furnished, but clean places where sick people may be sheltered and cared for by local physicians who are competent. The competence of the physician is more important than the quality of the building.

I have met Harrison of Arabia, who is the only physician in a large section of that country. He has a hospital which has no beds. His patients lie on concrete floors. He does an almost incredible amount of surgery with remarkably good results. He has no trained assistants, no trained nurses, very little material to work with, but he is himself a well educated and well trained surgeon. He is the hospital. He is a master craftsman.

Many country physicians possess comparable quality which has been developed through their ability to meet tragic emergencies with sole reliance on their own general knowledge. Many of them have developed overtones of personality which inspire confidence.

THE BASIS OF BETTER HEALTH

Better health for America would, of course, be promoted if medical help could be closely available to every citizen, but it is equally important that only well qualified medical help may be so provided. Medical organizations must set up criteria of competence of physicians who may be permitted to give medical and surgical care to our people. Hospitals facilitate good care, but the education of the physicians who administer it must be the concern of the councils of organized medicine as exemplified in the American Medical Association.

Planting physicians in industrial communities and subsidizing them by salaries or pay roll deductions has in some instances worked to the satisfaction of sick employees, and a fair quality of service has been delivered; but in other places incompetent or poorly equipped physicians held these places with a mere desire for subsistence rather than an ambition to bring good clinical medicine to people whose living standards were fixed as low as possible to satisfy the financial ambitions of their employers. These people had no personal choice of physician because none was available or permitted. Conditions comparable to a low type of European panel practice prevailed and provided poor medical service. Employment of physicians by membership societies,

lodges or other groups dominated by autocratic authority has frequently resulted merely in exploitation of the group by employing physicians at low salaries. For their services the members paid a periodic contribution and from this the management made a profit. Or perhaps a young physician who happened to be very competent but who needed the money was employed and exploited for an inordinate profit to the society or to some agent who had contracted to furnish medical service.

These promotions are going on and are attractive to speculators, who see an opportunity for rich material gain from enlisting people who desire to protect their future health through small periodic contributions. Where these organizations limit medical service to one physician or to a selected panel of physicians, the prospect of good medicine is not bright.

Many medical service plans involving free choice of physicians by the membership are in process of evolution and may be of great value as they merely limit the physician's fees according to commonly adopted schedules such as those provided by systems of workman's compensation.

Many hospital service plans promise ample satisfaction to subscribers and seem to be basically sound, provided they are honestly and intelligently administered.

All of these forms of delivering service to the sick need to be continuously studied by medical organizations in the interest of better health for all our people.

Although there is general harmony within our membership, there are occasional disagreements by small groups concerning policy which are generally met and satisfied in the regular process of the operations of county and state societies or in the deliberations of the national House of Delegates. There are sometimes small self-important groups which are unwilling to go through the routine county, state and national procedure and are so impatient that they jump the orderly freedom of fraternity, rebel against the thoughtful evolution of their great organization and parade their discontent in the public press.

It sometimes appears that they are selfishly dissatisfied with their own local environment and attempt to override the controlling opinions of their associates. They seem to be uncomfortable in any society. Their arguments are sometimes provocative and sometimes deserve the courteous attention they receive, but, unless they prevail, like spoiled children they sulk in their corners.

It sometimes appears that they are seekers after special privilege and desire special subsidies for their special operations.

These agitations and other unjustified technical appraisals of our public service have only served to strengthen our national organization, which has grown rapidly during the last four years as a responsive reaction among physicians to what they consider unjustified attacks.

Dividing the profession into groups of surgeons, internists, obstetricians, gynecologists, urologists, ophthalmologists, otologists, radiologists, pathologists is valuable for intensive scientific discussions and the results which may grow from them, but splitting the profession perpendicularly along the lines of creed or race or sociopolitical ideologies and developing rivalries and exaggerated desires for special privilege savors of the technics which have divided industrial workers into

classes, all fighting for what they consider their proportional rights. Such tendencies are subversive of the strength and effectiveness of the great body of American medicine, which should present a solid front in all efforts to promote public service in American health.

PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

You are all familiar with the text of the new platform of the American Medical Association. Every word of it is objective. It denies the allegation that the Association is reactionary and static and antisocial.

There is general agreement that the Association is moving consistently with conservation of real verities and real values, and that projection of new objectives promise to carry American medicine as a strong influence in the administration of the health programs of our country.

The American Medical Association stands for orderly and continuous progress toward better health for every American citizen. It stands for the elimination of every influence which may be destructive of the public health. It stands for the elimination of every communicable disease. It stands for the elimination of quackery. It stands for better general understanding of personal health problems. It stands for the promotion of research into fundamental causes of disease and curative therapy. It stands for better education of all physicians, not only the undergraduate but the general practitioner who has been long in service. Its platform stands for the coordination of all governmental health functions in order to promote efficiency and eliminate duplication of effort and wasteful extravagance of the people's money. It stands for the treatment of the sick in their homes by local physicians and welfare agencies—where the real individual troubles are known—and it desires as little interference by the central government as may be consistent with constructive relief of personal suffering. Its program is entirely forward looking and it seeks to carry it on in conformity with the best traditions of an advanced democracy.

The dictators of organized medicine are the practitioners of medicine, every one of whom has a voice which will be heard when it expresses a constructive thought even though it expresses adverse criticism. Nothing short of the best public service the organization can give will content the great body of medical opinion that is represented by the American Medical Association.

300 East Tremont Avenue.

Nonprotein Nitrogen.—The nonprotein nitrogen represents all of the nitrogenous constituents of the protein-free blood filtrate. The most important of these is urea. With the exception of the amino acids, these substances are end products of protein and nucleoprotein metabolism. Normally the substances are excreted at such a rate that their concentration in the blood is maintained approximately within the indicated limits, but with the development of renal insufficiency their excretion is diminished and hence they accumulate in the blood. Nonprotein nitrogen values in excess of 40 mg. per hundred cubic centimeters are indicative of nitrogen retention, and even figures above 35 mg. are somewhat abnormal. Since the consumption of large quantities of protein may cause a postprandial rise in nonprotein nitrogen, this factor should be kept in mind. In individuals from whom one kidney has been removed the nonprotein nitrogen tends to be somewhat elevated (40-45 mg.) even though the remaining kidney is entirely normal.—Bodansky, Meyer, and Bodansky, Oscar: *Biochemistry of Disease*, New York, Macmillan Company, 1940.

THE MANAGEMENT OF MECHANICAL OBSTRUCTION OF THE SMALL INTESTINE

DUE TO BANDS AND ADHESIONS

EDWARD J. LEWIS, M.D.

PHILIP SHAPIRO, M.D.

AND

ROGER T. VAUGHAN, M.D.

CHICAGO

Among important surgical conditions, none has been given more thought and attention, in recent years, than acute intestinal obstruction. Its frequency and persistently high mortality account for this bad eminence. The work of Wangenstein¹ and others has stimulated efforts to place the management of this disease on a more scientific basis.

The large public hospitals serve as unique clinical laboratories for the investigation of controversial medical and surgical treatments. Each surgeon bases his indications and procedures on his individual judgment and experience. Old and new methods are carried out simultaneously on identical groups of patients. Results of differing forms of treatment may be compared with a considerable degree of accuracy.

Study of the literature presents confusing and often paradoxical mortality reports for this disease.² Most of the reports group together all the acute mechanical obstructions. This study is limited to obstructions due to bands and adhesions. By limiting our study, we hope to clarify part of the picture.

Immediate operation has been the accepted indication for this type of obstruction either because strangulation is diagnosed or it is feared that strangulation is impending. A very considerable proportion of these patients, however, are suffering from nonstrangulatory ileus which can be relieved by nonoperative management. A proper selection of cases for this therapeutic trial demands careful study and a correct diagnosis. The combination of diagnostic and therapeutic maneuvers to be described has been used at the Cook County Hospital for several years. It is now followed in all but a few of the surgical services. The resident staff has given the procedures almost unanimous approval.

When the small intestine becomes involved in bands or adhesions following laparotomy or inflammation within the abdomen, a mild chronic obstruction may result without the patient becoming aware of its presence. The fixation or kinking of the bowel impedes the flow of intestinal contents. This mild impairment is compensated by thickening of the muscle coats. Symptoms appear only when the lumen of such a damaged bowel becomes blocked by a large meal of relatively indigestible foods such as coarse vegetables or dried fruits. An obturation ileus is superimposed on the chronic obstruction. In its early stages this acute obstruction often is incomplete. Even in the late neglected cases, a large proportion are nonstrangulatory. A previous laparotomy or a clear history of peritoneal inflammation without operation justifies the presump-

tion of adhesion ileus in such cases. However, one out of every seven cases in our series gave no history of previous abdominal complaint.

The differential diagnosis of the many conditions which might be confused with acute mechanical obstruction is well understood by careful observers and need not be discussed here. Locating the point of obstruction is important, as obstructions of the large bowel have only rarely been benefited by decompression maneuvers.

An attempt has been made to classify the cases used in this study on the basis of apparent severity at the time of admission. We have divided them into four groups, 1, 2, 3 and 4 plus. For this purpose the history of onset, frequency of the vomiting, severity of the colic and abdominal pain, amount of distention and degree of the obstipation were important criteria. Of much greater value were the examination of the abdomen, especially with the stethoscope, and the use of the x-rays, the stomach tube and the 2 quart enema.

Percussion of the abdomen yields a tympanitic note if distention is present. When the obstruction is in the small intestine, flatness is often noted in the right flank as the result of collapsed ascending colon and terminal ileum. Auscultation yields a pathognomonic sign of incomplete obstruction—obstruction borborygmus. These sounds result from vigorous activity of hypertrophied bowel when distended with gas or fluid. Their resonant or ringing timbre is characteristic whether the sounds are loud and booming or are only heard as a silvery whisper. They are heard only in the presence of some abdominal distention.³ Normal peristaltic sounds are fairly constant and are evenly timed. They become louder in the presence of slight obstruction. In the presence of greater obstruction there are short silent intervals followed by a rush of bubbling, resonant ringing sounds and then another period of silence. As the obstruction becomes more complete, the rushes become fewer and fainter and the silent intervals longer. The sounds also become higher pitched and may finally survive only as silvery metallic tinkles. With complete obstruction, the abdomen is silent. Abdominal tenderness is usually absent or mild as long as the obstruction remains incomplete. Strangulation is to be suspected when the onset is associated with intensely severe colics, when fever appears early and the course is rapidly progressive. In such cases abdominal tenderness is diffuse and more marked, rebound tenderness is often present, and there is considerable tenseness of the abdominal wall. Vomiting is early and violent, and the peristaltic sounds rapidly disappear.

The use of the fluoroscope and of x-ray films aids greatly in noting gas patterns and fluid levels as well as pneumoperitoneum, extra-enteric opacities and pathologic changes in the chest. It differentiates large from small bowel obstructions. The reappearance of gas in the colon is one of the earliest signs of relaxation of the obstruction.⁴

Enemas are used for diagnostic and therapeutic purposes at the same time. A 2 quart soapsuds enema may loosen a food or fecal plug as high up as the lower part of the ileum. These enemas also serve to cleanse the colon for subsequent fluoroscopy. The full amount

will rarely be taken when the obstruction is in the large bowel, especially if in the left side of the colon, where 85 per cent or more of such obstructions occur. The return enema is inspected for feces and blood (including the benzidine test). Subsequent enemas are watched for the appearance of the liquid petrolatum which has been previously administered by mouth and for flatus. Great care must be exercised not to administer air bubbles with the enema.

Criteria for classification of the patients into groups were as follows:

Group 1 plus had moderate incomplete obstructions, mild pains, slight distention and hyperperistalsis. They were free from abdominal tenderness and had normal temperatures.

Group 2 plus had marked but still definitely incomplete obstructions. They had moderate pains, vomiting and distention. There was slight abdominal tenderness, and auscultation revealed short silent periods alternating with peristaltic rushes and low pitched bubbling borborygmus. There was obstipation but no fever.

Group 3 plus were judged to be suffering from almost complete obstruction. There were vomiting, distention and marked colicky pains. Moderate abdominal tenderness was often present. The silent periods on auscultation were longer, there were fewer rushes, and the borborygmi were higher pitched and tinkling. Temperatures were normal or only slightly elevated.

Group 4 plus were definitely suffering from complete obstruction. This group included most of the strangulations. Pain was severe and persistent from the onset. Tympanites, persistent vomiting, and direct and rebound abdominal tenderness were present. Muscle tenseness simulated a true abdominal rigidity. The abdomen was completely silent except that a few high-pitched tinkling splashes could be heard on succussion. Occasionally a tense loop of bowel could be felt. The temperature was frequently elevated.

This group classification is tentative as far as the management of the cases is concerned. We have held to it in studying the progress of the patients and the end results of the treatment.

THERAPEUTIC MANAGEMENT

On admission, the patient's stomach is washed out by means of a large Ewald tube. From 2 to 4 ounces of liquid petrolatum is placed in the stomach before removing the tube. In slight obstruction, a substantial respite from vomiting follows. A 2 quart soapsuds enema is then given if an acute inflammatory condition within the abdomen can be ruled out. The patient is then examined by means of the fluoroscope.

With recurrence of vomiting, the Ewald tube is again used, or the Levine tube is inserted for continuous suction. Either method is effective in obtaining some decompression of the intestine. The nasal tube was used in only about half of our cases—the more severe ones, generally. Its use requires careful and constant supervision by a trained corps of attendants. Decompression relaxes the tenseness of the intestinal kinks and may possibly permit loops to slip out from under constricting bands. Exploration is facilitated if laparotomy becomes necessary later.

In the presence of vomiting, parenteral fluids are administered up to 4 liters daily, using 2.5 per cent dextrose in 0.45 per cent sodium chloride solution. These proportions result in an isotonic mixture. The specific gravity of the urine should be kept below 1.025 and the output maintained at or above 600 cc. in twenty-four hours. Blood transfusions are given before operation when indicated.

A heat cradle is placed over the abdomen. Morphine is allowed occasionally, but not to the clouding of the clinical picture. Liquid petrolatum is given again if

vomited, but only on the withdrawal of the Ewald or Levine tube. If oil appears in the enema, administration of the oil may be repeated daily, serving only to lubricate the bowel.

The period of therapeutic trial is continued if strangulation can be reasonably excluded. In cases of

and operation must be considered again. The high mortality with these delayed operations must be balanced against the fact that persistent suction, oil and enemas are sometimes necessary for four or five days before oil appears in the enema and the patient is definitely relieved.

RESULTS

This study includes all patients found to be suffering from intestinal obstruction due to adhesions or bands who were admitted to the Cook County Hospital during the years 1935, 1936 and 1937.

Table 2 records the mortality under various headings. The fifteen moribund patients died within fifteen minutes to twelve hours after entrance and received no significant treatment. Six patients submitted to interval operations after complete recovery from their obstructions. There were no postoperative deaths among these interval operations.

Table 3 indicates the operative mortality in relation to the duration of symptoms before operation.

Table 4 shows the mortality based on severity of the symptoms on admission.

No marked correlation was shown between the duration of the disease and the severity of the symptoms noted on admission. Table 5 illustrates this.

The clinical diagnosis of strangulation was checked against the observations at operation. This complication was diagnosed or suspected in fifty-four instances and was found in twenty-eight cases, or 52 per cent. The other twenty-six patients were found to be suffering from nonstrangulatory obstruction. As the patients in

strangulation most of the steps enumerated may be carried out in preparation for an early operation. In nonstrangulatory cases, if nursing facilities permit, the 2 quart enema is repeated every four hours or even more often. The liquid petrolatum normally reaches the colon in four hours. Its appearance is delayed in the presence of incomplete obstructions to twelve hours or even longer. Appearance of the oil in the expelled enema favors a continuation of conservative management. The other abdominal signs will also recede in the favorable cases. (A Richter type of hernia might show improvement for a time but rarely will be overlooked in a careful examination.)

At the end of twelve hours, a second examination is made under the fluoroscope. The patient is now well prepared for the operation, and the diagnostic work-up is fairly complete. The patients with strangulation, not yet operated on, will have progressed unfavorably in spite of the management described. They will now present the classic picture of a silent abdomen, rising temperature, abdominal tenderness and rebound tenderness. They should be operated on without further delay. The simple obstructions (obturations) tend to improve promptly or at least are no worse after twelve hours of this management. Vomiting lessens, intestinal sounds become less pathologic and the borborygmi become more booming and abundant. The silent intervals become shorter, and eventually gas and fecal material will appear in the enemas. We are encouraged to go on.

Table 1 shows the duration of obstruction in our nonoperative cases before the symptoms subsided.

It is to be noted that, in 70 per cent of the cases, symptoms subsided in the first twenty-four hours and, in 80 per cent, in the first thirty-six hours. Progress may be uneven and setbacks may occur. This is especially true when symptoms recur each time that suction is discontinued. The obturation has not been released

the strangulatory groups received almost immediate surgical attention (only six were in the hospital longer than twelve hours before operation) they furnish an indication of what might be called the minimal mortality to be expected from immediate [sic] operation. The nonstrangulatory patients in this group had a mortality of 25 per cent, and the patients showing strangulation at operation had a mortality of 30 per cent. Three patients with a diagnosis of strangulation entered the

hospital with diffuse general peritonitis. They all died without any attempt at operative intervention.

The clinical diagnosis of simple obstruction was also checked with the operative diagnosis whenever possible. Table 6 illustrates the observations, particularly on operation.

This table indicates clearly the mounting mortality rate when operation is finally performed after a prolonged therapeutic trial. When the patients with and without operation were studied on the basis of time intervals, and patients operated on were grouped with those who recovered under nonoperative management during the same period, the mortality was much more favorable. Such a grouping (table 7) has a more practical application when one is studying individual cases.

This greatly improved mortality is due to the large number of patients who responded to conservative management and went on to recovery without operation.

Ten patients died under conservative management in addition to the fifteen patients moribund on admission. Three of these deaths were from hypostatic bronchopneumonia in patients over 70 years of age. All three had been relieved of their obstruction for from one to several days before the pneumonia developed. One patient who appeared moribund on admission lived thirty-six hours under routine nonoperative management. One entered with a cardiac decompensation which dominated the picture throughout. One patient was irrational and violently uncooperative owing to cerebrospinal syphilis. Deaths of the remaining four patients may or may not have been avoidable. Two had no abdominal scars of previous operation. These two and a third entered with diffuse peritonitis which masked the obstruction. Two of the latter went to autopsy with a clinical diagnosis of salpingitic peritonitis. The fourth seemed to improve so promptly that strangulation was not seriously considered until peritonitis developed.

A previous abdominal operation was recorded in 203 cases and twenty-three others gave histories of peritoneal inflammations which subsided without any operation. The remaining thirty-six cases had no history of any previous abdominal complaint. In the male group the previous operation was appendicitis in 66.2 per cent

and one to five cases each of the following were noted among the remaining patients: gunshot, stab wound, closed injury of the abdomen, cholecystitis, ruptured peptic ulcer, ventral, inguinal and umbilical hernia. Nine males not operated on gave a history of attacks of appendicitis and one each of closed injury and of incarcerated hernia. Among six males without any previous history to account for their adhesions, two cases each were found to be due to terminal ileitis, appendicitis and Meckel's diverticulitis. Among female patients, 62.8 per cent gave a history of pelvic laparotomy and 22.4 per cent of operation for appendicitis. The remaining operations were for conditions similar to those observed in males. Six female patients gave a history of salpingitis, five of appendicitis and one of closed injury to the abdomen, all without operation. Among six females without previous history of abdominal complaint, tubal adhesions were found in three and endometrioma of the ileum, fibromyoma of the uterus and terminal ileitis in one each. The interval between the primary operation and the onset of obstruction varied from two weeks to twenty-five years in both sexes. No age group had any undue proportion of cases.

OPERATIVE MANAGEMENT

Exploratory operation was performed mainly for strangulation or for suspicion of strangulation. "Blind" ileostomy was done three times and only in the most desperate cases. All three patients died. Extensive incisions were usually unnecessary, the information obtained by careful preoperative study usually limiting the exploration to one or at most two quadrants of the abdomen. Evisceration of distended loops generally was avoided, the obstructing mass being usually identified by passing the hand into the abdomen. Small necrotic patches or discolored constriction rings were

inverted by Lambert suture. Side to side anastomosis was done in three cases for detouring obstructed loops, caught in an inextricable tangle. Most of the maneuvers consisted merely of cutting bands and releasing constricted loops. In the presence of gangrene of the bowel, exteriorization was the procedure of choice. The incision was then closed around the base of the loop and a delayed or immediate resection was performed, or the loop was drained immediately by catheter. Primary anastomosis after resection was reserved for the earliest cases with a minimum of distention. Ether was used

at some stage of the operation in 75 per cent of the cases; nitrous oxide was used alone in ten cases, local anesthesia in four cases and spinal anesthesia in thirteen cases. The mortality with spinal anesthesia was 30 per cent and with the other anesthetics was somewhat higher.

Table 8 lists the operative procedures and mortality.

COMMENT

Before the development of careful auscultation of the abdomen, x-ray studies and the continuous suction siphonage of Wangenstein, nonoperative management had a very limited field. It was followed for only 20 per cent of the patients admitted to the Cook County Hospital. Among 505 cases reported by Meyer and Spivack from the Cook County Hospital in 1934 there were 105 cases which subsided without operation, with the use of repeated gastric lavage, liquid petrolatum by mouth, and soapsuds enemas. In the three year period from 1935 to 1938, on which this report is based, almost 60 per cent of adhesion obstructions subsided under nonoperative management. The plan of management outlined has been accepted by all but a few surgical services. These few still favor the policy of immediate operation in all cases.

The mortality of surgically treated obstructions up to 1935 under the policy of prompt operation varied from 31 to 50 per cent (Vick, Vidgoff, Franken, Rentschler). In the Cook County Hospital a mortality of from 45 to 48 per cent was reported by Meyer and Spivack⁵ and by Cubbins and Fey.⁶ Although these statistics included all types of mechanical ileus, from 70 to 74 per cent of the obstructions were due to adhesions and bands.

By treating 60 per cent of our patients by nonoperative measures, instead of 20 per cent as in the previous series, we have removed from the surgically treated group forty patients of each 100 admitted. As the mortality rate for surgical cases was previously from 45 to 48 per cent, approximately half of these patients have been saved, i. e. twenty lives in each hundred cases. Deducting the loss of four lives among each 100 cases treated conservatively, there remains a net gain of sixteen lives per hundred cases.

Forty-four per cent of the patients were operated on with a mortality of 33 per cent. While this rate is still high, it compares favorably with published reports of cases under immediate operative management. We may expect improvement from the more general use of blood transfusions, especially in the cases of strangulation, and from the more frequent use of spinal anesthesia. It is probable that 10 per cent of the patients—twenty-four of the ninety-six operated on—would not have been operated on at all if the therapeutic trial maneuvers had been in use in all the surgical services of the hospital. There were nine deaths among these twenty-four patients, although three of the deaths from hypostatic pneumonia were probably unavoidable. Sixteen other patients grew worse under conservative management persisted in for more than thirty-six hours. At operation only one showed a strangulated bowel, but the mortality of this group was 50 per cent. With experience in handling these persistent obstructions, conservative treatment might be continued for a longer time before resorting to operation.

One advantage of the plan of diagnosis and management herein outlined has no statistical exhibit. It abets accurate diagnosis. Many patients admitted as having intestinal obstruction are found, after the diagnostic routine and brief period of observation, to have non-operative ileus due to uremia, pneumonia, coronary thrombosis, lead colic, gastric crisis, salpingitis or puerperal infection. They may have questionable operative lesions such as appendical abscess, acute cholecystitis, acute pancreatitis or colon diverticulitis, requiring further observation or surgical attention directed to the primary lesion. The patients thus saved from harmful operation far outnumber the few with obstruction who might have been better off under the policy of immediate operation.

As shown in table 5, no close correlation was established between the duration of the disease and the mortality. More important factors were the completeness of the obstruction and the presence or absence of strangulation. The severity of the symptoms on admission depended principally on the type of pathologic condition present. It is perhaps of special importance to note that twenty-six of the ninety-four patients with complete obstruction in group 4 plus improved so promptly under preliminary preparation that operation became unnecessary. However, fourteen of the eighty-eight with almost complete obstruction in group 3 plus became worse under therapeutic trial and were finally operated on because strangulation was feared. None of the patients operated on had a second operation in this hospital for recurrence during the entire three year period of study.

The amount of time and close attention that this type of case demands is far greater than is required for most abdominal conditions. Only by the closest observation and cooperation on the part of the resident staff, nurses and attendants has improvement in results been achieved. A special team devoted entirely to the problem of intestinal obstruction and covering all wards in the hospital may be expected to reduce the mortality still further.

CONCLUSIONS

1. Under the plan of diagnosis and management here presented, 56 per cent of patients with acute intestinal obstruction due to bands and adhesions recovered without operation.
2. Although the mortality of patients coming to operation was 31 per cent, the total mortality of all treated patients (including surgical) was 17 per cent.
3. In 80 per cent of the nonsurgical group obstructions subsided within thirty-six hours; the remainder required two, three, four or five days before their obstructions were relieved.
4. Strangulation was found in only 52 per cent of the obstructions so diagnosed or suspected before operation. The remainder proved to be simple obstructions.
5. The type of pathologic condition is the most important factor in the mortality and in the severity of the symptoms on admission. The duration of the obstruction is of secondary importance.
6. A minimal operative mortality of 25 per cent in simple obstruction, operated on immediately, and of 30 per cent in strangulatory cases, also with operation on entrance, is indicated from this study.
7. A more general application of the management here presented may be expected to reduce the number of patients requiring surgical intervention to about 30 per cent of those entering the hospital with this disease.

PECTIN-AGAR FOR DIARRHEA IN
INFANTS AND THE NEWBORNA RATIONAL, SIMPLE AND EFFECTIVE
TREATMENT

PHILIP J. HOWARD, M.D.

DETROIT
AND

CHARLES A. TOMPKINS, M.D.

OMAHA

Since the earlier reports¹ on the use of pectin-agar feedings in diarrhea of infants, continued experience has added much to our knowledge of its use and effectiveness. The treatment is safe and valuable in enteritis of the newborn, and it is also a simple method, adaptable for home use, in treating older infants and children. The mixture is made by cooking a soluble prepared powder in milk or other suitable liquid. The composite action of a high carbohydrate food containing pectin and agar results in an easily digested nutritious food which mechanically produces formed stools, favors normal peristalsis, absorbs and adsorbs bacteria with their toxins, systemically combats ketosis, protein catabolism and dehydration, chemically combines with certain bacterial toxins and catabolic body wastes, and locally promotes healing. A few remarks on rationale, application of simple modes of use and the effectiveness of the treatment follow.

PREPARATION AND ADMINISTRATION

Because of certain disadvantages found in the use of the apple diet² it seemed desirable to design a preparation retaining the good qualities inherent in apple therapy and overcome, if possible, the disadvantages. The only two elements of apple diets proved to have value are pectin and cellulose.³ With this in mind the following preparation⁴ was designed: pectin 6.3 per cent, agar 4.3 per cent and dextrimaltose 89.4 per cent. One cup or 8 ounces by volume of the resultant powder equals approximately 480 calories. This basic mixture lends itself well to the making of diets particularly designed for nurslings and young children respectively.

In preparing a formula for nurslings 1 cup of the powder is cooked ten minutes in a double boiler with 24 ounces of milk. While still hot the desired amount is poured into nursing bottles. After cooking a gel results calorically equal in milk and added carbohydrate, each ounce of which contains 40 calories. On being rewarmed and shaken the preparation easily feeds through a nipple with an enlarged opening. Newborn babies take this formula with ease and it is well tolerated and retained. The usual feeding schedule is continued. Since the number of calories per ounce in this mixture is twice that usually given, the volume offered is reduced to about one half and the difference is made up by giving water between feedings. The end result

in milk, water and carbohydrate administration is the same as when mixtures containing 20 calories per ounce are given. By preparing the pectin-agar without water it is possible to produce the desired gel state and still maintain a well proportioned adequate food. The thick, low volume feeding reduces the tendency to vomit. The prepared formula does not give up liquids readily, so hydration must be assured by giving oral or parenteral fluids between feedings.

For children from 6 months to 2 years of age, one cup or 8 ounces by volume of the powder is cooked for ten minutes in a double boiler with 16 ounces of milk or other suitable liquid. If fruit juices are used the preparation is cooked in a part of the liquid, the remainder being added immediately after cooking to retain the natural flavor. Vanilla, cocoa, bitter chocolate, fruit and other foods may be added to suit the taste (Washburn¹). To rewarm place the container of food in hot water. The preparation may be frozen for children who prefer it cold.

The treatment of diarrheas at any age consists of limiting all intake to the pectin-agar formula and water until the stools are formed. The therapeutic result is good whether large or small amounts are taken, the bulk of the stool depending on the intake. The older infants and children are allowed as much of the food as desired. After the bowel movements are free from blood, pus and mucus and are formed, the best practice with nurslings is gradually to replace the pectin-agar feeding with a formula in which calories from milk and added carbohydrate are equal and the volume of milk equals the volume of water, the resultant mixture containing 20 calories per ounce, or with milk and carbohydrate in a proportion similar to that found in the pectin-agar formula for nurslings. In a few days the infant is returned to a standard milk formula approximating a milk-carbohydrate caloric ratio of 2:1. Another method of transition is gradually to decrease the amount of pectin-agar mixture and add water when preparing the formula. After the proportions become one-half cup of the powder (240 calories), 24 ounces of milk (480 calories) and 12 ounces of water, the mixture contains 20 calories per ounce with a milk-carbohydrate ratio of 2:1. At this time the special formula may be replaced with a standard milk mixture. In older children transition is made by gradually replacing pectin-agar feedings with gelatin desserts, toast, jelly, banana, apple, baked potato, cottage cheese and lean meat. Milk, vegetable and cereal should be added with caution.

RESULTS IN DIARRHEA OF THE NEWBORN

The accompanying table shows the results of treating a series of twenty-three newborn infants with enteritis. As a whole these infants were not systemically very ill, the maximum temperature being 102.4 F. rectally and this probably in part from dehydration. The single constant feature was the presence of bright red blood in the feces varying in amount from slight streaking of the stools to gross blood and mucus. On proctoscopic examination in some instances, bleeding points about the size of pinheads appeared on an otherwise apparently normal mucosa. A mild diarrhea occurred in all but three infants. None of the stools contained pus. These babies were fretful and on occasion took feedings poorly; however, weight gain was satisfactory for the neonatal period, including one premature infant (S. L.). All infants treated with pectin-agar had soft stools within forty-eight hours, while the remainder of

the group continued to have liquid stools for about one week or more. The table shows the definite difference in the number of liquid evacuations in the infants treated with the pectin-agar formulas. While the time factor might account for a decrease in watery stools as a normal course of events, all the infants were placed

during which time the baby gained 150 Gm. This observation has been repeated many times among older infants with a decrease from over twenty-five liquid stools in twenty-four hours to three or four soft ones the following day. The average percentage of the stools which were liquid in the group on standard feedings

on this diet because the feces were becoming more liquid and frequent or were failing to improve satisfactorily, and too rapid a change from pectin-agar formulas back to a standard feeding resulted in an exacerbation in symptoms. One patient (B. P.) included in this series became ill the second day after birth. The feces contained blood and mucus and were liquid. On the day pectin-agar was started there were sixteen stools. The next day there were four soft passages with no gross blood. The special formula was given for three days

was 55 as contrasted with a fall to 10 per cent as an average while the patients were on pectin-agar formulas. The mean number of days until all liquid stools became soft and normal appearing was 4.7 with standard feedings as contrasted with a fall to 1.6 days with pectin-agar.

The specific etiologic agent in these cases of enteritis was not proved, but *Bacillus cloacae* and streptococci capable of fermenting mannite were found in the stools of most of the sick infants in contrast to twelve normal

babies in whose stools no streptococci were found and in only one instance *B. cloacae*. When a pure culture of the latter was injected intravenously into rabbits a diarrhea resulted. This organism is not usually considered pathogenic for man.⁵

RESULTS IN DIARRHEA OF OLDER INFANTS AND CHILDREN

Approximately fifty infants and children with bacillary dysentery and other types of diarrhea have been treated in the home with gratifying results. Hospitalization is avoided because the stools promptly become formed, hydration is maintained, vomiting is minimal, calories are adequate to assure weight gain, the food is usually well taken because of the adaptability to various tastes, the infants are less fretful because of decreased tenesmus and absence of hunger, and finally chronic intestinal infection is less frequent. Starvation regimens and bad tasting diets fail to fulfil most of the criteria just mentioned. Formed stools usually appear the next day after the diet is begun if no other food is permitted. Transition to a regular diet may be begun the second or third day of treatment except in cases of true enteritis due to dysentery or other pathogenic bacteria. In these infants the therapeutic diet should be continued until blood, pus and mucus disappear from the stools.

The following case report is typical of the results obtained with this treatment for the various types of diarrhea after the first half year of life:

REPORT OF CASE

An infant aged 8 months was under observation and treatment for lymphatic leukemia. The accompanying graph shows the clinical course of a diarrhea that developed in conjunction with various associated parenteral infections. It is noteworthy that liquid stools promptly appeared when an orange juice, salt and sugar mixture, protein milk, dextrose-saline or standard formula was given, but the stools always became soft or formed in less than twenty-four hours with pectin-agar administration. The actual number of liquid passages undoubtedly exceeded those recorded, as bedside observation of the infant while it was on liquid diets revealed an almost constant passage of flatus and watery, mucous stools. A short time after pectin-agar administration the passages and flatus diminished, and bowel sounds decreased. The diarrhea was probably based on the parenteral infections and reflex irritation from leukemic infiltration of the mesenteric lymph nodes and Peyer's patches as shown at autopsy. The bowel mucosa was found to be intact.

RATIONALE

For various reasons an increasing number of clinicians deem it rational and, when possible, advisable to give high carbohydrate diets to infants suffering from acute gastrointestinal disturbances, particularly if associated with parenteral infections. First, these conditions tend to decrease food tolerance by diminishing gastric secretion and by altering gastrointestinal motility with increased and sometimes reversed peristalsis. So it seems desirable to give an easily digested, simple, high carbohydrate food rather than high protein foods, which because of their complex nature are more difficult to digest. Secondly, these infants have an increased metabolic rate due particularly to the hyperpyrexia. So there is increased catabolism in an individual with a digestive tract that may have a decreased ability to supply the demands. Since simple carbohydrates are easily digested and assimilated, the decreasing liver

glycogen is more readily replenished and the ketosis with its possible compensatory vomiting, resulting from protein and fat catabolism, is less likely to develop. Newborn babies, particularly if premature, often do better on a high carbohydrate formula as their caloric requirements are higher than subsequently and it is at this time that they are very susceptible to diarrhea and digestive upsets. This pectin-agar preparation fulfills the requirement of a high carbohydrate formula and in addition it is more digestible, possibly owing to the acidity of the pectin, its colloidal action and its ability to precipitate the milk into a very fine curd, a physico-chemical phenomena that does not alter the taste.⁶ Whatever the underlying mechanism for increasing food tolerance, the fact remains that very sick infants often easily tolerate concentrated pectin-agar formulas of various carbohydrate, fat and protein combinations, even up to over 100 calories per ounce. This preparation has been used as a basic formula to which powdered milk combinations, carbohydrates or other foods are added to increase calories in a tolerable, antiketotic

Clinical course of diarrhea in an infant aged 8 months.

genic, low volume feeding. Such a procedure has been helpful in treating marasmic babies with or without diarrhea, premature infants or infants with vomiting based on pylorospasm or ketosis resulting from acute infections. The ease with which these pectin-agar formulas are utilized adds an important factor to their rationale and usually obviates the necessity of starving sick infants that need normal or increased caloric intake.

In the original publications it has been shown that nickel pectinate preparations are bactericidal under proper conditions of heat and acidity.⁷ Arnold⁸ has repeated these experiments with confirmatory observations; however, it has been shown⁹ that pectin decreases bacterial growth only to the extent that the pH is lowered and that the presence of pectin does not increase the

W., and Winters, Matthew: Bactericidal Action of Pectin Containing Nickel, *Proc. Soc. Exper. Biol. & Med.* 39: 478 (Dec.) 1938.

toxicity of nickel for *Escherichia coli*. The therapeutic effect of pectin-agar powders prepared with nickel pectinate and other pectins has been essentially the same, and the acidity of pectin is neutralized in the intestine; so it seems unlikely that the results of this treatment are dependent on a bactericidal effect.

Many feel, in cases of diarrhea in infants, that the bowel should be put relatively at rest by withholding oral food and in some instances even water. It does not necessarily follow that the empty gastrointestinal tract is at maximum rest. Some children on such a regimen have almost constant green passages containing mucus and flatus. Starvation favors the ascent of *Escherichia coli* into the upper bowel with secondary gas formation. This fact and the hunger contractions superimpose the well recognized mechanism of starvation diarrhea. In such instances, on listening to the abdomen with a stethoscope, one readily gets the impression that there is still much to be desired in the way of putting the bowel to rest. These pectin-agar diets of the types just described allay hyperperistalsis and actually put the bowel relatively at rest as compared with starvation regimens, as evidenced by the prompt decrease in bowel sounds, flatus and stools even before the gel has had time to pass through the gastrointestinal tract.

Pectin and cellulose have been shown by Malyoth,⁹ Baumann and Forschner-Boke¹⁰ and others to be the only components in apple that, if destroyed, result in a poor effect from apple therapy. Scheer¹¹ has reported good results from agar-milk preparations and stresses the importance of agar in mechanically giving formed stools and cleansing the gastrointestinal tract. Pectin on hydrolysis releases arabinose, galactose, methyl alcohol and up to over 90 per cent galacturonic acid. Glycuronic acid, an isomer of galacturonic acid, has long been recognized as a chemical detoxicant for certain catabolic products and ingested poisons. Manville and his co-workers¹² report experimental evidence suggesting that pectin has the power of forming conjugation products similar to glycuronic acid and that the administration of pectin has a glycuronic acid sparing effect. Uronic acids are important in the synthesis of mucin and, if the demands for detoxication are too great, mucus secreting elements are impaired with a tendency toward ulcer formation. Winters, Peters and Crook¹³ have shown that pectin heals and prevents experimental peptic ulcers in dogs. Manville, Bradway and McMinis¹⁴ suggest that pectin also has a protein sparing effect by decreasing the demands for glycuronic acid formed in part from glycogenic amino acids resulting from the breakdown of body proteins.

Many articles have been published on the values of pectin as a hemostatic agent.¹⁵ Recent experimental data throw some doubt on its effectiveness in actually

controlling bleeding.¹⁶ In the cases studied, blood did not promptly disappear from the stools, however, sooner than with other forms of treatment. The passage of blood decreased in proportion to the healing of the ulcerations, as evidenced by proctoscopic examination. It would seem, therefore, that there is more rapid healing of the bowel mucosa but no direct hemostatic effect.

The role of pectin *per se* in controlling the symptom diarrhea seems to be as yet not completely determined. Block and his co-workers¹⁷ report that nickel pectinate is effective in treating acute and chronic dysentery. Owing to the natural tendency for remissions and exacerbations of symptoms in these cases, regardless of therapy, it is difficult to draw conclusions from a small series. These authors state that pure pectin is ineffective. This opinion is not held by others, who report good results in treating various types of diarrhea with pure pectin;¹⁸ however, Wilke lays more stress on the systemic improvement and states that pectin does not produce as well formed stools as apple or banana. Experience with the University of Indiana group in treating both adults and infants with nickel pectinate revealed no definite help in controlling the liquid stools; in fact, in most instances evacuations became more liquid and frequent, so that it was necessary to discontinue the therapy. There was, however, possibly some evidence of systemic improvement. In our experience the use of nickel pectinate alone has been unsatisfactory in treating infants and children. Any systemic improvement has been offset by a lack of control of the diarrhea or an exacerbation of the symptom. Our results have been equally good whether nickel pectinate or other pectins have been used in the pectin-agar powder. Any treatment to be satisfactory during infancy must control the liquid stools promptly. So the sum total effect of the pectin-agar-dextrin-maltose formula may be summarized as follows: 1. Pectin retains any value it may have as a detoxicant, adsorbent and healing agent. 2. It is in a vehicle which promptly controls the symptom diarrhea. 3. The preparation results in a high calory, high carbohydrate, well tolerated food which tends to combat ketosis and vomiting.

SUMMARY

1. The method of preparing and administering pectin-agar formulas for nurslings and older children is simply cooking 8 ounces by volume of pectin-agar powder into 24 or 16 ounces of milk.
2. In a series of twenty-three cases of enteritis in the newborn, complete recovery occurred in all. Nine infants in the group were treated with pectin-agar formulas which proved helpful and practical.
3. Excellent results were obtained in treating older infants and children. The simplicity and effectiveness of the pectin-agar regimen lends itself particularly well to treating infants and children at home.
4. The rationale of this therapy depends on the combined effects of the pectin-agar combination in well tolerated, antiketogenic, highly nutritious formulas.

POTASSIUM SALTS IN THE TREATMENT OF POLLINOSIS

A CLINICAL EVALUATION

SIMON S. RUBIN, M.D.

ABE L. AARONSON, M.D.

MORRIS A. KAPLAN, M.D.

AND

SAMUEL M. FEINBERG, M.D.

CHICAGO

The evaluation of therapeutic results in hay fever has always been a difficult task, primarily because of the absence of objective methods of study. Since it is necessary to evaluate such therapy by subjective means, the patients must be studied under close scrutiny and with a view to the natural variations in conditions which modify the course of the disease. It has been shown repeatedly that the severity of hay fever symptoms in the individual depends chiefly on the concentration of pollen in the air. These concentrations vary geographically, seasonally and daily. Failure to employ these considerations in arriving at opinions of various types of hay fever treatment has been responsible for a large number of the enthusiastic, but usually short lived, new therapeutic methods.

In 1933 one of us¹ presented a method of evaluation of therapeutic results in hay fever. This consists essentially of daily grading of the symptoms of a number of patients under experimentation and their comparison with a control group of hay fever patients as well as comparison with the pollen counts.

In the present undertaking our aim was to evaluate the currently proposed potassium chloride treatment of hay fever. Bloom² had reported that he obtained strikingly beneficial results with the use of potassium salts in twenty-nine cases of hay fever. Potassium chloride given in 5 to 10 grain (0.32 to 0.65 Gm.) doses three times daily gave good results, in many patients the symptoms disappearing within a few minutes. The results in chronic asthma were poor, many patients having their symptoms increased. In a second paper, Bloom and Grauman³ extended their series of hay fever cases to sixty-one, in practically all of which there was response to this therapy. A number of other allergic cases were added and in most of these, with the exception of asthma, good results were claimed. Even cases of "chronic sinusitis" showed a high incidence of improvement. In neither of these papers is there any evidence indicating that the authors observed these patients with reference to variations in pollen counts and comparison with control hay fever groups. There is not even any clear statement describing the types of pollinosis on which these experiments were made.

To a series of twenty-seven allergic patients, mostly children, of whom thirteen had seasonal hay fever or asthma, Abt⁴ administered potassium chloride in doses of 2½ to 5 grains (0.16 to 0.32 Gm.) three times daily. Good results were obtained. Fortunately the author

included the dates on which the treatment was begun in the individual patient. It is interesting to note that in the seasonal cases of asthma and hay fever the earliest date on which this medication was administered was October 20. Since it is well known that pollinosis in Chicago terminates before the end of September it is readily apparent that the conclusions are based on false premises. Had Abt failed to give any dates, which is the case with most authors, this report might have been considered substantial evidence in favor of potassium chloride.

It may be mentioned that prior to these reports on hay fever therapy Rusk and Kenamore⁵ had described a small group of patients with urticaria who received partial to complete relief for varying periods of time while on a high protein, low sodium, acid ash diet, with added potassium chloride. Later, Rusk and his co-workers⁶ found that, while certain allergic patients with symptoms of urticaria and asthma showed definite relief with the use of potassium chloride alone or combined with insulin, others did not seem to benefit by this treatment. From their investigations they were unable to determine which allergic patients will show a therapeutic response.

Harley⁷ described a series of forty-three patients suffering from hay fever, allergic rhinitis, asthma, urticaria and eczema in whom potassium chloride therapy failed to produce any significant degree of improvement.

CLINICAL OBSERVATIONS

Prior to the ragweed hay fever season we had studied a group of nonseasonal cases of allergy such as asthma, perennial rhinitis and urticaria. When the first symptoms of ragweed pollinosis were noted in 1939 a group of patients was placed on potassium therapy. Later, when the season was well established, an additional group was treated similarly. Two types of observations were made: the immediate effects on the symptoms and the more prolonged influence of this medication.

In a group of thirteen patients the immediate effects of potassium salts were observed. Five patients with hay fever were given 15 grains (1 Gm.) of potassium chloride with no improvement in four noted by the patient or observer in the period of one hour. One patient stated that she had a little clearing of her nose. Three patients with moderately severe hay fever were given 30 grains (2 Gm.) of potassium gluconate. In two no improvement was noted, while in the third instantaneous temporary clearing of the nose resulted. This relief was later reproduced in the same patient by a drink of cold water. Of three patients with hay fever and asthma, two obtained no relief after a dose of 15 grains of potassium chloride while the third had an exacerbation of the asthma. In two other patients with hay fever and asthma the use of 30 grains of potassium gluconate gave no relief in the period of one hour.

In a study of the effect of prolonged administration of potassium salts, 153 patients with hay fever or hay fever with asthma received potassium chloride or potassium gluconate for periods varying from several days to a few weeks. The usual dose for adults was from 10 to 15 grains of potassium chloride or from 15 to 30 grains of potassium gluconate three or four times daily. The dose for children was from 5 to 10 grains of potas-

sium chloride three to four times daily. Potassium chloride was dispensed in a vehicle of distilled water, syrup of glycyrrhiza, or syrup of sweet cherry. Potassium gluconate was dispensed in 5 grain tablets. The patients were directed to take their medicine with an abundance of water. In order not to rely on the patient's memory, they were instructed to keep an accurate written daily report of all their symptoms. It was noted that of the 153 patients only seven patients experienced mild relief while 146 patients obtained no relief. Two of the 153 patients became worse. One patient with idiopathic epilepsy who was free from symptoms for almost a year had a recurrence of his seizures. Three patients experienced epigastric pain and gastrointestinal upsets following the ingestion of potassium chloride. These symptoms were not present when they were taking potassium gluconate.

In order to make accurate comparisons with groups of similar patients not receiving potassium salts our group of 153 patients was divided as follows:

1. Patients with hay fever symptoms who had inadequate or no specific desensitization therapy. This group comprised thirty patients, twenty-eight receiving potassium chloride and two potassium gluconate. No improvement could be observed in twenty-seven of these patients, while two had mild relief and one was made worse.

2. Patients with hay fever and asthma who had inadequate or no specific desensitization therapy. Of fifty-two such patients fifty received potassium chloride and two potassium gluconate. Only two patients taking potassium chloride obtained mild relief. The remainder had no improvement.

3. Patients with hay fever who had adequate specific desensitization therapy but had remaining symptoms. There were twenty-four patients in this group. None received any benefit. One had gastrointestinal symptoms from the potassium chloride, which was eliminated by the substitution of the gluconate salt.

4. Patients with hay fever and asthma who had adequate specific desensitization but had remaining symptoms. Of forty-four patients in this group forty had no benefit. Mild improvement was noted in three patients and marked aggravation of the symptoms occurred in one patient. Three patients had gastrointestinal upsets from the potassium chloride.

In the groups of patients who had remaining symptoms, observations were made to see whether these symptoms would be improved.

Daily pollen counts were made and a curve representing the daily concentration of pollen for the entire ragweed season was charted. It was noted that the severity of the symptoms followed rather closely the changes of pollen density. It was also noted that after the administration of potassium salt the symptom curve continued its normal course. Worthy of emphasis was the dipping down of the symptom curves with the dipping down of the pollen curve. Had not the pollen counts been sufficiently considered, any therapy at this point would have been deemed a success.

Potassium chloride was also used in nonseasonal cases of allergy for periods lasting from five days to three months. Fifteen asthma patients received potassium chloride. Six were worse while on this therapy and four showed no improvement. Nine patients with perennial allergic rhinitis showed no improvement on potassium chloride. One patient had polyps that did not decrease with this therapy, so they were removed surgically. In six cases of angioneurotic edema or

urticaria two showed temporary improvement. In three cases of dermatographism the therapeutic effect of potassium chloride was questionable.

Thus, after evaluating the results of potassium chloride in the individual patient and comparing groups of patients with similar groups which did not receive potassium chloride, we are forced to the conclusion that potassium salts have no practical usefulness in the treatment of hay fever. Moreover, it was definitely noticed that some of the asthma patients were worse while on potassium. Whether patients with urticaria, angioneurotic edema and dermatographism definitely improve on this medication remains to be seen from further observation on a greater number of patients. Our group of patients was too small.

SUMMARY

1. Potassium salts were of no practical therapeutic value in our series of 153 patients with hay fever and seasonal asthma.

2. The effect of such salts in other allergic conditions is highly questionable.

3. Reports of therapeutic results in hay fever should be received with skepticism unless they bear the earmarks of evaluation by methods based on relationship of the symptoms to daily, seasonal and geographic fluctuation of the pollen counts.

HAVERHILLIA MULTIFORMIS SEPTICEMIA

ITS ETIOLOGIC AND CLINICAL RELATIONSHIP TO
HAVERHILL AND RAT-BITE FEVERS

F. F. ALLBRITTEN, M.D.

R. F. SHEELY, M.D.

AND

W. A. JEFFERS, M.D.

PHILADELPHIA

It has long been known that the bite of a rat may be followed by a recurring fever. In the orient such a syndrome has been recognized for centuries and has been called sodoku. The recovery of more than one type of organism from patients having a fever after a rat bite has led to considerable confusion. When an infecting agent has been recovered from patients so stricken, it has usually been one of two organisms: In the majority of instances *Spirillum minus* (*Spirochaeta morsus muris*) has been thought to be causative. From a few patients, however, an entirely different organism, *Haverhillia multiformis* (*Streptobacillus moniliformis*, *Streptothrix muris ratti*), has been recovered.

Although it might be expected that the clinical picture would vary according to the infecting agent responsible, such a clinical differentiation has not yet been clearly established. Instead, as each new case has been reported, the author has usually proposed that the organism which he recovered must be the cause of "rat-bite fever." The history of this controversy can be read in the editorial pages of *THE JOURNAL*,¹ where comments have appeared periodically since 1915, the latest being in the issue of Sept. 2, 1939. We believe that

¹From the William Pepper Laboratory and the Edward B. Robinette Foundation, medical clinic of the University of Pennsylvania Hospital. This article is abbreviated in *THE JOURNAL* by omission of an extensive bibliography for table 1. The complete article appears in the authors' reprints.

evidence is accumulating to allow of a clinical as well as an etiologic differentiation between two diseases which have heretofore been confused and grouped together under the name "rat-bite fever."

As its name suggests, *Haverhillia multiformis* is also the organism recovered from patients with Haverhill fever (*Erythema arthriticum epidemicum*). There was no history of rat bite preceding the illnesses of those who suffered in the epidemic of 1926 in Haverhill, Mass. One is thus confronted with three diseases: sodoku, *Haverhillia multiformis* septicemia following rat bite, and Haverhill fever. The same infecting agent is concerned in the last two, but the mode of infection differs.

It is our purpose in this paper (a) to point out the similarities between Haverhill fever and fever following rat bite due to *Haverhillia multiformis* septicemia, (b) to show that the *Haverhillia multiformis* infections present clinical features distinguishing them from rat-bite fever (sodoku) due to *Spirillum minus*, and (c) to indicate methods for the laboratory diagnosis of the diseases under consideration.

REPORT OF CASE

R. B. E., a man aged 21, was bitten on the left thumb by an albino rat Aug. 2, 1938, while working in a medical laboratory. Three days later he awoke with malaise and in the early afternoon suffered a severe chill lasting for thirty minutes. He was admitted that day to ward D in the University of Pennsylvania Hospital, in the service of Dr. O. H. Perry Pepper.

The clinical course is shown in the accompanying chart. On admission there was insufficient evidence of local or systemic disease to account for a fever of 105 F. The wound of the bite on his left thumb had healed and subsequently showed no evidence of inflammation. He was somewhat disoriented; the mucous membranes of the throat and eyelids were slightly congested; there was moderate generalized enlargement of the lymph nodes, but the spleen was not palpable. The physical examination was otherwise negative. The family background and the past medical history did not prove of importance to the present illness.

The initial laboratory examinations revealed hemoglobin 80 per cent, white blood cells 32,000, neutrophils 80 per cent, lymphocytes 16 per cent and eosinophils 4 per cent. Urinalysis showed no abnormalities. Cultures taken of material from the throat, of the sputum and of the stool revealed no predominating pathogen. The blood serum did not agglutinate *Bacillus typhosus*, *Brucella abortus*, *Bacterium tularensis* or *Bacillus proteus* X₂ and X₃. The Wassermann reaction of the blood gave negative results during (and after) the illness.

Two features of the clinical course were noteworthy: cutaneous lesions and arthritis. On the second day of the illness a maculopapular rash appeared over the lower part of the chest and the upper part of the abdomen. The lesions were discrete, being from 3 to 5 mm. in diameter, and faded on pressure. With the subsidence of the fever the rash disappeared, only to become evident again during the second paroxysm. At this time the lesions tended to be confluent. They involved the distal halves of the extremities, including the palms and the soles. This rash persisted for four days. Dr. Robert Shaffer made a diagnosis of toxic erythema. On the tenth day several tender nodules were noted on the finger tips. A day later these were purpuric, and in the succeeding two days a yellow umbilicated center developed. No pathogenic organisms were found on culture and dark field examination of one of the nodules taken for biopsy. Dr. Herman Beerman reported that microscopic sections from one of these cutaneous lesions showed an inflammatory reaction of nonspecific character. During the second paroxysm of fever many small petechial and purpuric spots appeared over the lateral aspects of the feet. On the fourth day of the illness there was marked tenderness over the symphysis pubis and stiffness of the right knee and left elbow. These symptoms subsided after forty-eight hours. On the fifth day the patient complained of severe pain in the left shoulder. This did not subside until the last week of hospitalization,

despite the application of an airplane splint to immobilize it in abduction. On the forty-third day the left hip became stiff and painful. The involved joints were not aspirated, since there was no evidence of effusion. Repeated roentgenograms of the affected joints were negative. During the paroxysms of fever the lymph nodes of the left axilla became swollen and painful.

From the twelfth to the sixty-eighth day of his illness the patient was given potassium iodide from 30 to 90 grains (2 to 6 Gm.) daily—the smaller dose being used after the appearance of a pustular iodide eruption. After the second bout of fever, the hemoglobin having fallen to 68 per cent, a transfusion of 500 cc. of citrated blood was given. Progressive improvement ensued. The temperature fell to normal and the patient gained weight and was discharged from the hospital September 8. On the fifty-sixth day after the onset semiweekly injections of from 0.1 to 0.5 Gm. neoarsphenamine were started and continued in ascending doses to a total of 2.5 Gm. Two days after the first injection of neoarsphenamine the stiffness in his left hip subsided and the temperature, which again had been ranging between 99 and 100 F., fell to normal and remained there. At present, more than a year later, the only sequelae are an occasional twinge of pain in the left hip and persistent enlargement of lymph nodes in the left axilla.²

On the third day of the illness dark field examinations of the blood, lymph node fluid and scrapings from the cutaneous lesions were negative for spirilla. On the fifth day, blood from the patient was inoculated into white mice and guinea pigs.

Temperature (F.) in a case of *Haverhillia multiformis* septicemia: B. C., blood culture; R., rash; A., arthritis; T., transfusion; Neo., neoarsphenamine.

Subsequent dark field examinations of the blood of these animals were made at two day intervals for a month but no spirillar forms were seen. The animals remained well.

Blood cultures taken on the first, fourth and seventh days of the disease showed growth of *Haverhillia multiformis* in plain broth and brain broth mediums after two days of incubation at 38 C. The bacteriologic characteristics of this organism were identical with those described by Parker and Hudson.³ Intraperitoneal inoculation of a white mouse with 1 cc. of a broth culture of the organism caused polyarthritis and other characteristic lesions.⁴ The animal died on the fourteenth day after inoculation. The organism was recovered from cultures of its heart's blood. We found it impossible to divide the organisms by prolonged shaking, resuspension or supersonic fragmentation methods into a homogeneous antigen suspension suitable for testing agglutination. Twelve rats from the colony which our patient had been tending were examined by the methods described by Strangeways.⁵ *Haverhillia multiformis* could not be isolated. Dark field examinations of the blood and nasopharyngeal secretions of the same animals were negative for *Spirillum minus*.

This syndrome of intermittent fever, morbilliform and petechial cutaneous eruptions and arthritis has been observed following rat bite and has been likened

2. An insurance company is to be compensable, resulting from an

to the clinical picture of Haverhill fever by Scharles and Seastone⁶ and by Farrell, Lordi and Vogel.⁷ The etiologic agent causing the two diseases is *Haverhillia* multiformis. In the case of Haverhill fever the portal of entry has not been proved, but Place and Sutton⁸ suggest that the original epidemic was probably milk borne.

A third disease, called sodoku by the Japanese, has been shown by Futaki⁹ and others to be due to infection with *Spirillum minus*. It is characterized by an indolent primary lesion and lymphangitis occurring at the onset of fever, followed by a papular or large macular eruption, from which the organism can occasionally be recovered. An intermittent fever may persist for many months. Arsenic is specifically curative. This disease has been observed most frequently in the orient,¹⁰ but sporadic cases have occurred on this continent¹¹ and in South America.¹² The experimental inoculation of man and certain animals¹³ with this organism has resulted in an infection resembling syphilis.

Certain similarities between the two types of fever following rat bite have led, until recent times, to their being considered variants of the same disease. The

fever and cases which we adjudged to be Haverhill fever on account of their clinical and bacteriologic features were reviewed. Only those reports including some clinical data, supported by bacteriologic confirmation, were thought to be suitable for tabulation. This survey revealed 111 cases of sodoku (*Spirillum minus* isolated), sixteen cases of *Haverhillia multiformis* septicemia following rat bite, five cases of fever following rat bite from which both *Spirillum minus* and an organism resembling *Haverhillia multiformis* were said to have been recovered, and sixteen cases of Haverhill fever not associated with rat bite. It was hoped that a tabulation of the clinical features of each would show significant differences between the *Haverhillia* and the spirillar diseases. That this was not the case may be explained by the fact that the completeness of our review is manifestly limited by the extensiveness of the diagnostic study in any particular instance. The earlier reports, particularly, were apt to include only fragmentary accounts of the clinical and laboratory aspects.

In spite of these difficulties, certain features stand out as tending to differentiate the spirillar form (sodoku) of rat-bite fever from the type produced by *Haverhillia multiformis*. These features are shown in

TABLE 1.—Occurrence of Clinical Features According to Syndrome and Etiology

history of rat bite, the fever and the occurrence of cutaneous lesions at first glance make the two seem related. Furthermore, it has been shown that laboratory and wild rats can act as carriers of both *Haverhillia multiformis*⁵ and *Spirillum minus*.¹⁴ Although certain observers, such as Futaki,¹⁵ who are well acquainted with sodoku have pointed out clinical differences between the two diseases, their impressions have not been supported by adequate evidence.

We have therefore reviewed the accessible literature for instances of fever following rat bite, from which either *Spirillum minus* or *Haverhillia multiformis* (or both) was recovered. Particular attention was paid to the clinical course. In addition, all reports of Haverhill

table 1. From this tabulation it appears that fevers due to *Haverhillia multiformis* are characterized by arthritis and a small macular rash, as compared with rare joint involvement and a papular or large macular eruption when *Spirillum minus* is concerned. When infection with *Haverhillia multiformis* has followed the bite of a rat there may be no exacerbation of the wound, marked leukocytosis is common, and the period of incubation is apt to be brief. The arsphenamines have been effective in the treatment of fever following rat bite due to either organism and probably should be given a further trial in Haverhill fever. From our review of the literature we have also noted that (1) the bite of a laboratory rat usually produces an infection with *Haverhillia multiformis* rather than with *Spirillum minus*, and (2) the febrile paroxysms resulting from *Haverhillia multiformis* infection are less regularly periodic than those due to *Spirillum minus*.

The *Haverhillia multiformis* infections thus appear to occur as septicemias with metastatic arthritis and morbilliform and petechial cutaneous eruptions. The picture is similar whether infection has occurred by rat bite or otherwise (e. g. through the mouth as is probably the case in Haverhill fever). The bite wound is likely to heal readily. The systemic involvement is paramount.

By contrast, when *Spirillum minus* is concerned (sodoku) the bite wound may become a chronic indurated chancre with lymphangitis; the cutaneous lesions

are large, frequently elevated and never petechial, and metastatic arthritis does not occur.

In order that these clinical differences can become more clearly delineated, reports in the future should include the result of a search for both organisms. The procedures involved are outlined in table 2. Further details can be obtained on reference to the papers of Bloch and Baldock,¹⁶ and of McDermott.¹⁷ The possibility of the spontaneous occurrence of spirilla in the blood of laboratory animals should not be forgotten.¹⁸

Through appropriate laboratory investigations other problems can be approached: Does simultaneous infection with *Spirillum minus* and *Haverhillia multiformis* often occur in man following rat bite? Is neoarsphenamine of definite value in the treatment of diseases due to the bacterial organism? Both bacillary and pleuropneumonia-like forms have been described in cultures of *Haverhillia multiformis*¹⁹ but their exact relationship is not yet understood. In the light of Swift's²⁰ report of having recovered pleuropneumonia-like organ-

arthritis and morbilliform and petechial cutaneous eruptions.

2. *Spirillum minus*, entering the body through a rat bite, may produce changes comparable to those seen in syphilis—i. e. chancre, papular or large macular cutaneous eruptions and fever. Arthritis is very rare.

3. When a combination of the features mentioned are observed following the bite of a rat, a mixed infection may be suspected.

ROLE OF ALKALI THERAPY FOR PEPTIC ULCER IN FORMATION OF URINARY CALCULI

C. WESLEY EISELE, M.D.

CHICAGO

When peptic ulcer is treated by the customary methods, which involve the ingestion of large amounts of alkaline powders, several conditions are produced which are generally accepted as important etiologic factors in the formation of urinary calculi. It has been shown¹ that during a Sippy type of treatment the urinary excretion of solids is doubled, the specific gravity of the urine is high (the average twenty-four hour specimen having a specific gravity of 1.020) and the p_H of the urine is shifted to the alkaline side. These three conditions have been mentioned many times as important etiologic factors in the development of kidney stones. Because peptic ulcer is a common disease and because the use of large amounts of alkali is a popular form of treatment, it would be expected that in any large series of patients with urinary lithiasis there would be a significant number who had received treatment for peptic ulcer prior to the onset of lithiasis.

A survey of recent literature concerning the etiology of urinary lithiasis indicates that peptic ulcer therapy has received scant or negligible attention in this role. Most authors fail to mention it at all.² Goldstein and Abeshouse³ made an extensive review of the literature up to 1937, but they do not refer to peptic ulcer or its treatment. Cabot⁴ states that "some patients, whose diet is planned in such a way as to require a high alkaline intake such as is indulged in by patients with gastric and duodenal ulcers, do tend to develop stone." On the other hand, Priestley and Osterberg⁵ state that "it is extremely uncommon for patients who follow a prolonged medical regimen for the treatment of peptic ulcer which entails the consumption of large quantities of alkaline substance to have a urinary calculus." In

TABLE 2.—Laboratory Diagnosis of *Haverhillia Multiformis* and *Spirillum Minus* Infections

Procedure	<i>Spirillum Minus</i>	<i>Haverhillia Multiformis</i>
Blood culture	No growth on ordinary mediums	Draw blood at height of fever; add to beef bouillon; characteristic growth in 24 to 96 hours; ascitic fluid or serum enrichment of mediums needed for all subcultures
Animal inoculation	Inoculate mice and guinea pigs intraperitoneally with 2 cc. of citrated blood or material aspirated from bite wound or adjacent enlarged lymph node; daily dark field examination of inoculated animal's blood for <i>Spirillum minus</i> ; if <i>Spirillum minus</i> is found before 5th day, it is probably a natural infection	Inoculations with patient's tissue fluids give negative results; inoculations of cultures into mice result in polyarthritis and death; not pathogenic for rats and guinea pigs
Tissue fluids	Dark field examination of patient's blood; serum from wound or involved lymph node (rarely positive); stained preparations of tissue fluids by Wright's, Gram's or Fontana's stain (rarely positive)	Centrifuge joint fluids and examine smears; take culture of joint fluid in ascitic or serum bouillon
Serologic reaction	Technically difficult and of questionable value	Positive agglutination, precipitin and complement fixation may offer confirmatory evidence

isms from exudates of patients having rheumatic fever, it is possible that *Haverhillia multiformis* may prove to play a part in diseases of man other than Haverhill fever and septicemia following rat bite.

SUMMARY AND CONCLUSIONS

From our observations on a patient suffering from *Haverhillia multiformis* septicemia after rat bite, together with a review of the literature pertaining to infection with this organism and with *Spirillum minus*, the following impressions are presented:

1. *Haverhillia multiformis* infections, acquired by rat bite or otherwise, usually produce septicemia with

a number of textbooks and monographs on urology⁶ no reference to peptic ulcer treatment was found.

Similarly, the literature dealing with the treatment of peptic ulcer is almost uniformly silent concerning urinary calculi as a possible complication of alkali therapy.⁷ Brown and Dolkart,⁸ in a critical review of the various methods of peptic ulcer treatment, do state that "it has been alleged that the incidence of renal calculi in patients who have been receiving alkaline powders over extended periods is far too high to be considered insignificant." No reference for this statement is given.

It is of interest that one of the conditions present during ulcer treatment, namely the ingestion and excretion of large amounts of crystalloids, has long been recognized as a standard method for producing kidney stones in laboratory animals. Keyser,⁹ Snapper and Polak¹⁰ and others have done extensive work in this field, producing stones in animals by the feeding of calcium carbonate, calcium oxalate and oxamide. Many authors believe that there is an analogous clinical syndrome in man. Keyser has named this "hyperexcretory calculosis." One would expect that the alkali treatment for peptic ulcer would be one of the chief examples of this syndrome, but I have not seen it so mentioned. The examples cited usually include the excessive excretion of oxalates, phosphates, uric acid, cystine, xanthine, leucine, and the hyperexcretion of calcium phosphate in hyperparathyroidism. A number of these conditions are admittedly rare. Livermore¹¹ states that he has never seen a case of xanthine stone. Hyperparathyroidism as a cause of nephrolithiasis has received much attention of late, yet in most institutions this disease is considered a rarity. The omission of peptic ulcer therapy from the list of examples of hyperexcretory calculosis, a list which includes such rare examples, would lead one to conclude that peptic ulcer treatment has seldom been observed in this role.

Although one would expect from theoretical considerations a high incidence of treated peptic ulcers in a series of urinary lithiasis cases, a survey of the literature suggests that this is not so. Because of this discrepancy, the present study was undertaken.

MATERIAL AND METHODS

The clinical records of all patients of the University of Chicago Clinics bearing the diagnosis of kidney or ureteral lithiasis were obtained from the diagnostic files. The study included all cases seen during the period extending from the founding of the Clinics, Oct. 1, 1927, to July 1, 1939. Both outpatient and hospital admissions were included. The clinical records of these patients were examined to determine if any previous diagnosis of peptic ulcer had been made. The duration of ulcer symptoms and the type and duration of ulcer treatment were noted, as well as the duration of urinary symptoms and the occurrence of any other systemic pathologic condition. Only ureteral and kidney stones were included in this study, for it has been shown by Winsbury-White,¹² Shivers and Henderson¹³ and others that bladder stones are found almost exclusively behind mechanical obstruction and usually in the presence of infection, thus placing them outside the considerations of this study.

RESULTS

The Incidence of Calculi in the Upper Urinary Tract.—During the twelve year period of this study, 223,110 new patients were admitted to the University of Chicago Clinics. The diagnosis of ureteral or kidney stone was established for 505 of these patients. Thus the incidence was one in 442 new patient admissions.

Of the lithiasis series 343 patients were males (67.9 per cent) and 162 were females (32.1 per cent), giving a sex ratio of 2.1 to 1. The age range was from 16 months to 76 years with an average age of 42.3 years. No important difference in age distribution between the two sexes was noted. The duration of symptoms at the time of the first observation ranged from a few hours to thirty-four years, averaging 3.8 years. (When there were recurrent attacks, the duration was calculated from the onset of the first attack.)

The Incidence of Peptic Ulcer in Patients with Urinary Calculi.—Forty-four patients in the urinary lithiasis series also had peptic ulcers. The ulcer history had antedated the onset of urinary stone symptoms in every case except one. This one case was excluded from the series used in the present study. The forty-three patients with preexisting peptic ulcer represented 8.5 per cent of the total lithiasis series. There were thirty-seven males and six females, giving a sex ratio of 6.2 to 1. The average age was 45.1 years and the age distribution curve by decades closely followed that of the entire lithiasis group.

The duration of ulcer symptoms prior to the onset of the stone symptoms averaged 8.3 years, with a range from six weeks to twenty-five years. In only one case had the ulcer been present for less than two years; and in thirty cases, or 70 per cent of the series, the ulcer symptoms had existed for five years or more prior to the onset of the stone symptoms.

The type and duration of ulcer treatment were difficult to determine in some cases. For purposes of this study, the series was divided into the following groups: (a) Eighteen of the patients received ulcer treatment

at the clinics before the onset of their stone symptoms. A modified Sippy treatment was used, involving frequent doses of alkali powders (usually sodium bicarbonate, calcium carbonate and magnesium oxide). Many in this group had also received some treatment before being treated here. The duration of treatment at the clinics, prior to the onset of lithiasis symptoms, ranged from one month to eight years, with an average of two years. In nine cases, or half of the group, treatment had been administered for between one and two years, and in five for less than one year. (b) Sixteen patients had stone symptoms at the time of their first observation here and had had a Sippy type of treatment elsewhere prior to admission here. (c) Nine patients had stone symptoms at the time of their first visit here, but the details and duration of their prior ulcer treatment were uncertain. All in this group had been diagnosed as having peptic ulcer and had received some type of treatment. For seven of this group, it is recorded that alkali provided relief of distress, so probably most of them received some form of alkali therapy.

Seventeen patients (40 per cent) had suffered ulcer complications, ten had had hemorrhages, two had had perforations and six had had pyloric or duodenal obstruction. Five had undergone surgical treatment for their ulcers.

In addition to the forty-three patients who had received peptic ulcer treatment there were thirteen patients who had chronic gastrointestinal distress for which they had habitually taken alkalis for relief and in whom the habit had become established prior to the onset of urinary symptoms. These represent 2.6 per cent of the series. Thus there was a total of fifty-six patients, or 11.1 per cent of the lithiasis series, in whom the ingestion of alkalis may have played a role in the formation of the urinary stones.

Other Conditions Outside the Urinary Tract.—The table lists other conditions outside the urinary tract. No attempt was made to study any pathologic involvement of the urinary tract other than lithiasis, for this was deemed to be outside the scope of the present study.

COMMENT

There are several possible explanations for the occurrence of peptic ulcer in 8.5 per cent of our series of patients with urinary lithiasis: 1. Peptic ulcer and urinary lithiasis may have a common cause, possibly

a common constitutional background. This conception is highly speculative, as in neither disease is etiology understood. 2. Urinary lithiasis may be a cause for the development of peptic ulcer. This hypothesis has been discussed by Welch, Coplan and Holmes.¹⁴ They have shown that urinary lithiasis causes a prolonged reflex spasm of the stomach and duodenum, thus producing a definite ischemia of the mucous membranes and thereby interfering with the nutrition and resistance of the mucosa. This hypothesis is attractive, but it does not seem applicable to our cases as the peptic ulcer antedated the stone symptoms by an average of 8.3 years. In only one case (not included in the series) did the onset of the stone symptoms precede ulcer symptoms. It is unlikely that the stones remained silent in all forty-three cases for so many years. 3. The ulcer itself may be an etiologic factor in stone formation. There is no evidence to support this view. 4. Alkali treatment for peptic ulcer may cause lithiasis. It is this hypothesis which most nearly satisfies the conditions of our data. Onset of lithiasis symptoms after the institution of treatment speaks strongly for this relationship. This view is further strengthened by the great similarity between the conditions present in alkali treatment and in certain experimental methods used to produce kidney stones in laboratory animals. The hyperexcretion of crystalloids produced by excessive feeding of substances such as calcium carbonate and calcium oxalate has been widely used to produce experimental kidney stones. As has been mentioned, the operation of this mechanism in other clinical situations is generally recognized. Keyser¹⁵ writes as follows: "Clinically, the evidence for hyperexcretory calculus is abundant. Phosphaturia, oxaluria and uratic showers in gouty disease are known to be frequently associated with stone. Cystine calculi occur with the excessive appearance of an abnormal crystalloid in the urinary tract. The high incidence of calcium phosphate calculi associated with hyperparathyroidism is especially illuminating. Here we have an excessive parathyroid secretion with consequent hypercalcemia, hyperphosphatemia, hypercalciuria and hyperphosphaturia. In short, there is intensive hyperexcretion of calcium phosphate. Hypercalculus thus approaches the point of establishment as a clinical entity." With such a marked increase in the urinary excretion of crystalloids during alkali therapy, one wonders how this condition has escaped heading the list of clinical examples of hyperexcretory calculus. Our observations, summarized in the table, emphasize the rarity of certain examples usually cited; that is, gout, hyperparathyroidism, cystinuria and xanthinuria.

A sweeping condemnation of the use of alkalis in ulcer therapy is not intended by this study. Our only purpose is to warn the clinician of another potential danger in the intensive use of alkalis. Once recognized, this danger can be guarded against more effectively. The occurrence of alkalosis has long been known as a possible complication of ulcer therapy. As a known pitfall, it has guided the clinician in a more rational course of treatment. Similarly, a knowledge of the possibility of hyperexcretory calculus complicating the course of ulcer therapy may lead to better treatment.

No attempt has been made to determine the incidence of urinary lithiasis in a series of treated peptic ulcer

patients. Such a study would involve the difficult and often inaccurate method of following the subsequent course of patients after they have been under treatment. Peptic ulcer is notoriously a chronic disease and, such being the case, its victims are apt to drift about seeking medical attention from various sources, thereby making their subsequent course inaccessible in many instances. Those patients in whom complications develop which they may consider to be due to their treatment are especially apt to be disgruntled and to ignore a questionnaire, thereby giving faulty sampling. Consequently it is believed that the present method of study gives a more accurate picture as it deals with the past history of patients as recorded on their clinical charts rather than with future developments.

The occurrence of gallstones in twenty-four patients (4.8 per cent) probably is not significant, as they are found in from 5 to 10 per cent of all patients coming to autopsy.¹⁶ However, this observation is not in agreement with Young.¹⁷ He believed that the coexistence of gallstones and urinary stone is infrequent and found only thirteen such instances in 527,000 roentgenograms during a ten year period. Ezickson¹⁸ suggests that there is a relationship between hepatic dysfunction and renal lithiasis.

The occurrence of calculus in twenty patients with diseases causing bone destruction is significant. This probably represents another example of hyperexcretory calculosis, although infection and prolonged immobilization are other factors to be considered in some of the cases. Goldstein and Abeshouse,¹⁹ Pulvertaft,²⁰ Sisk²¹ and others have written concerning this problem.

CONCLUSIONS

1. In a series of 505 patients with kidney or ureteral stones, there were forty-three, or 8.5 per cent, with preexisting treated peptic ulcers.

2. There were an additional thirteen patients, or 2.6 per cent, who had chronic gastrointestinal complaints for which they habitually took alkalis.

3. Thus there were fifty-six patients, or 11.1 per cent, in whom the ingestion of alkali powders may be considered of etiologic importance in the formation of their urinary stones. This is in agreement with theoretical considerations and constitutes the clinical counterpart of stones produced experimentally in laboratory animals by the feeding of crystalloids.

4. The hyperexcretory calculosis which developed in these patients demonstrates a potential danger of alkali therapy for peptic ulcer.

NOTE.—Since this manuscript was completed, a paper by H. L. Kretschmer and R. C. Brown appeared in *THE JOURNAL* (Oct. 14, 1939, p. 1471) entitled "Do Alkalis Used in the Treatment of Peptic Ulcer Cause Kidney Stones?" In a series of 1,260 cases of kidney and ureteral stone, they found only fifteen cases with a history of treated peptic ulcer, or 1.2 per cent. They conclude that theoretically one might expect the alkalis used in the treatment of peptic ulcer to cause renal stone but that the small incidence they found does not support this theory. I am unable to explain the discrepancy between their data and mine.

COMBINED (ACTIVE-PASSIVE) PROPHYLAXIS AND TREATMENT OF DIPHTHERIA OR TETANUS

GASTON RAMON, M.D.

GARCHES, FRANCE

It was stated recently in *THE JOURNAL*¹ that "fifteen years ago Ramon and Laffaille² suggested a new method of prophylaxis against diphtheria. By this improved method the transient passive immunity caused by injecting antitoxic serum is supplemented by a semi-permanent active immunity caused by the simultaneous injection of diphtheria toxoid." Then Frey and Schmid's³ work on the subject was referred to and this conclusion was drawn: "Combined active-passive immunization is not feasible in human medicine, the two types of immunization being incompatible with each other." It was stated: "Frey and Schmid injected 2,000 units of antidiphtheric serum . . . into each of twenty children, followed by single or multiple subcutaneous injection with diphtheria toxoid," whereas in the original text Frey and Schmid stated that their patients received 1,000 or 2,000 antitoxic units intramuscularly simultaneously with 1 cc. of alum toxoid (unsere Patienten erhielten 1.000 bzw. 2.000 Antitoxineinheiten intramuskulär sowie 1 ccm. Alumtoxoid subkutan). The particular fact of single or multiple injection of anatoxin is of great importance. I shall come back to a discussion of it later on.

As was recalled in *THE JOURNAL*, I pointed out with André Laffaille in 1925 that when an injection of tetanic anatoxin is made into a guinea pig in another part of the body the immunizing action of the anatoxin is more or less hindered by the antitoxin. However, this first injection of anatoxin is not useless, for the animal can later be immunized by a second injection of anatoxin alone. This fact led me to the conclusion that active immunity against tetanus is easily produced in laboratory animals by injecting one or, better, two doses of anatoxin some time after the simultaneous injections of antitetanic serum and anatoxin. The results of the experimentation have been the basis of the "combined active-passive prophylaxis and treatment of diphtheria or tetanus."

In 1926, with Christian Zoeller,⁴ I tried this technic in human medicine. Tests made on adults (soldiers) showed that an active antitetanic immunization could be realized by simultaneous injections of antitetanic serum and anatoxin, followed by one or several doses of anatoxin at more or less long intervals. On the basis of these well established principles, serovaccination against tetanus was soon actively put into practice. Over a long period (twelve years) the available results have brought confirmatory evidence of our first attempts.

Thus in France (1933) Sacquépée⁵ gave valuable data concerning 240 wounded men who had received the combined (passive-active) immunization against tetanus according to our method, i. e. simultaneous injections of antitetanic serum and anatoxin and at intervals of two or three weeks two injections of ana-

DIPHTHERIA AND TETANUS—RAMON

2367

toxin alone. Six months later, 234 men (more than 97 per cent) had an antitoxic response to tetanus equal to one-fiftieth unit or higher. The level stood generally between one-fifteenth and one-fifth unit; this titer is quite a satisfactory immunity.

Patients treated by serovaccination have the same antitoxic response to a subsequent "reinforcing dose" of anatoxin injected several months or a year later, or later still, as patients who have been vaccinated with anatoxin alone. That fact was mentioned in Zoeller's paper. The effectiveness of this "reinforcing dose" has been clearly demonstrated by Sacquépée and Jude⁶ in an extensive and valuable study. Among fifty-one patients who had been given a reinforcing dose of tetanic anatoxin (2 cc.) after having received, on account of a wound, a combined passive-active immunization, 96 per cent showed, six months later, an antitoxic response still in excess of one-third unit; thirty-six (76 per cent) showed a response of over 1 unit, some of them reaching 10 or even 30 units.⁷ This rise in antitoxic titer is identical with the rise following previous vaccination with anatoxin alone.⁸ It appears that an active, strong and permanent immunization can be induced by serotherapy combined with specific anatoxin vaccination.

The principle having been worked out and the practical results being confirmatory, a new treatment of acute tetanus was created. The technic was recently⁹ established by some of my co-workers and myself—Kourilsky, Mme. Kourilsky, Richou, Maccolini.¹⁰ It consists in injecting, as soon as the diagnosis is made, a single and large dose of tetanic antitoxin (150,000 international units, i. e. 75,000 U. S. P. units) and 2 cc. of tetanic anatoxin. Gradually progressive doses are then repeated at intervals of five or six days—2, 4 or 6 cc. for instance. Later, reinforcing doses of anatoxin may be given; they are harmless and of real benefit. Experimental investigations and clinical tests made on patients have brought evidence that active immunization due to injections of anatoxin follows without interruption the passive immunization due to serotherapy. After a reinforcing dose, patients treated with this method have been found with an antitoxic titer of 20 and 50 units per cubic centimeter of blood serum. This method for tetanus prophylaxis, combining both serotherapy and anatoxin therapy, is not only of a great theoretical and doctrinal interest but has become highly important on account of the European conflict.

Simultaneously with this new method of prophylaxis against tetanus, experimentally established in 1925 and applied to human medicine in 1926, a new method of prophylaxis against diphtheria was introduced. Since then the method has been extensively applied in France to immunize nonvaccinated children after a sudden exposure to a widespread diphtheria epidemic. The method is as follows: An injection of diphtheria anatoxin (toxoid) is made and a few minutes later an injection of antidiphtheric serum. The vaccination is completed with two injections of anatoxin at a fort-

night's interval. Under these conditions the active immunity due to repeated doses of anatoxin is easily superimposed on the passive immunity due to antidiphtheric serum. The fact has now been clearly demonstrated in France, where the method has been used for over fifteen years and concerns thousands of persons.

As I first mentioned in 1925, and Frey and Schmid last year, a single dose of diphtheria toxoid, whether as alum-toxoid or not, given simultaneously with an injection of antidiphtheric serum produces only a minimal immunity if any at all. The fact was observed by Paschla¹¹ after it had been observed by many other authors. In a way, the same might be said of a single dose of anatoxin given without an injection of serum. The insufficient protection afforded by the "one dose immunization" has been emphasized by many investigators besides myself.¹² Only persons having a certain amount of diphtheria antitoxin naturally in their blood serum show a rise of the antitoxic titer after an injection of anatoxin given simultaneously with an injection of serum. When two subsequent injections of anatoxin are given under the same conditions, the picture is quite different, the resulting immunity having all the characteristics of active immunity acquired through usual vaccination.

The possibility of producing active immunity against diphtheria by one injection of serum and several injections of anatoxin has also been demonstrated by a new method in the treatment of diphtheria identical with the one now used for tetanus. A massive dose of antidiphtheric serum is first given (20,000 to 80,000 units according to the patient's age), then repeated doses of anatoxin (0.1 cc., 0.5 cc., 2 cc., 3 cc. and so on) at four or five day intervals, the first dose of anatoxin being injected a few minutes before the serum. At my request this method was applied in some of the Paris hospitals by Robert Debré and Mallet,¹³ René Martin, Delaunay and Richou,¹⁴ Sohier and Jaulmes,¹⁵ Girod¹⁶ and others. More than 200 children or adults have been treated in this way for the last two years. Serologic results afforded by the charts of the antitoxin content of each patient's blood serum confirmed experimental data and gave evidence that a large dose of antidiphtheric serum does not prevent successive anatoxin injections from producing the appearance and development of active immunity. When patients suffering from diphtheria are treated with both serum and anatoxin, the active immunity succeeds without interruption to the passive immunity due to the repeated doses of anatoxin depends on the individual. Some persons never develop a high antitoxin level and attain that slowly (average of one-third unit). Others have a detectable antitoxin a few days after the injection, the antitoxin titer rising abruptly, reaching 30 or 50 units or higher still. During the period of illness and convalescence, and even long afterward, the antitoxin level in most cases, if not in all cases, is sufficient to insure protection against recurrent attacks of toxoinfection.

Animal experimentation and numerous investigations carried out over a long period in human medicine have given proof that combined immunization, when correctly applied by one injection of serum and repeated injections of specific anatoxin, (a) is able to superimpose uninterruptedly active immunity on passive immunity, thus insuring a permanent antitoxic immunity against tetanus or diphtheria, (b) realizes the best prophylaxis against tetanus for the nonvaccinated wounded patient and against diphtheria for the nonvaccinated child who runs a special risk of infection, and (c) gives a better chance of success in the treatment of tetanus and diphtheria.

Clinical Notes, Suggestions and New Instruments

A PLEA FOR THE ABOLITION OF THE RETENTION CATHETER IN THE PREPARATION OF PATIENTS FOR PROSTATIC SURGERY

RICHARD P. MIDDLETON, M.D., SALT LAKE CITY

Few therapeutic measures in urology are more unquestioningly accepted by the profession than the urethral retention catheter in the preparation of patients for surgery directed to the relief of prostatic obstruction. Notwithstanding this almost universal approbation, it is my purpose to plead, on grounds of personal experience and what I consider sound logical considerations, for the abolition of this time-honored device.

Thompson¹ has called attention in recent years to the uselessness or even harmfulness of routine retention catheter preparation for patients whose renal function is essentially normal as shown by dye excretion tests and blood chemistry examinations. My own experience has confirmed this suggestion, and most patients are now submitted to prostatic resection forthwith, as soon as studies have indicated a satisfactory general condition and adequate renal function. In deference to tradition, however, I still cling to a short period of catheter preparation in those cases in which the residual urine is large (over 300 cc.), even if renal function tests are essentially normal. It is therefore with these patients and those whose kidneys are obviously impaired to an important extent that this communication concerns itself.

The transurethral surgical approach to the prostate has perhaps made all urologists more careful students of the anatomy and pathology of the vesical neck and deep urethra. In the course of some hundreds of prostatic resections I have been consistently impressed by the strikingly unfavorable change in the appearance of the bladder and urethra produced by the retention catheter. Following even a short period of such continuous drainage, the vesical neck is uniformly engorged and edematous. Some degree of diffuse cystitis prevails, and the dome of the bladder regularly exhibits an angry spot of bullous edema from catheter contact, which the experienced cystoscopist is accustomed facetiously to demonstrate to the tyro as a carcinoma of the bladder.

The external indications of this cysto-urethritis are only too familiar to all urologists—the more or less tender urethra with crusted mucopurulent exudate clinging to the tape which fastens the catheter to the penis, and the not infrequent copious oozing of pus around the catheter.

Several years ago I began to wonder whether the retention catheter is not a double-edged sword. Is not operation through a highly inflamed edematous urethra analogous to celiotomy through a pyodermic area or to enucleation of a cataract in the presence of acute conjunctivitis? A method of achieving the undoubted benefits obtained with the retention catheter while avoiding its iniquitous results should be a real boon to urology.

Such a method has been found by resort to interval catheterization, a device which has brought vast and increasing satisfaction during the past three years. No longer are catheters

strapped in. Every three or four hours a male nurse or specially trained orderly slips in a catheter, empties the bladder, and immediately withdraws the catheter. Patients are not disturbed for catheterization during the customary hours of sleep but are relieved if they awake and are uncomfortable. Once daily (or oftener when marked pyuria exists) the bladder is irrigated with 1:5,000 potassium permanganate solution. I believe that irrigations and instillations can be overdone and that frequent chemical irritation of the vesical mucosa may do more harm than good.

The advantages of this technic will soon be apparent to any who try it. Purulent urethritis in the prostatic patient becomes nothing but a memory. Patients are decidedly more comfortable. Since they are not tethered by tubing, physical activity remains unimpaired. At operation the vesical outlet and prostatic urethra appear delightfully free from redness and swelling. Bullous edema is conspicuously absent, a fact of great importance in view of the accurate orientation with respect to ureteral orifices, the verumontanum and other landmarks demanded of the resectionist. Furthermore, I am convinced that preparation by interval catheterization instead of the retention catheter reduces operative hemorrhage and tends to promote smoother convalescence. That this is more than a fond delusion is indicated by the fact that I have been able to convert my local colleagues to this belief.

Several urologists to whom this plan has been described have raised the question whether interval catheterization restores renal function as rapidly as does the retention catheter. Their doubt seems superfluous when it is recalled that the method most closely simulates normal physiologic emptying of the bladder. Granted that the patient's needs are met by complete emptying at intervals of several hours, as is true of the rest of mankind, it would seem illogical to ask him continuously to suffer the trauma of a retention catheter in the interim. It is pertinent to recall that the patient with tabes or any other man who has resigned himself to "catheter life" never wears his catheter but practices momentary insertions as being far less damaging to his urethra.

Other urologists, in personal discussions of this question, have suggested that repeated passage of a catheter might be expected to result in more infection from bacterial contamination than if the catheter was passed once and fastened in place. That this is specious reasoning is indicated not only by my experience but also by the recent work of Stalker and Schulte,² who remark: "Patients with postoperative urinary retention following general surgical procedures are best treated by frequent intermittent catheterization whenever possible. This can usually be done for a period of three to four days or longer without the development of evidence of urinary tract infection. In a case in which a retention catheter has been used, infection invariably develops in twenty-four to thirty-six hours. Once bacteria have developed they rapidly increase in number while the catheter is retained. When intermittent catheterization is employed the increase is not so rapid and in some cases even a decrease is noted." There seems little doubt that constant wearing of a catheter causes much more infection than repeated passages, granted reasonably good technic.

With the retention catheter some rise of temperature during the period of preoperative preparation is admittedly not an uncommon phenomenon. Indeed, there are those who see it as a hidden blessing, a "vaccination" of the urinary tract against postoperative infection. For example, Davis³ says: "In fact a period of fever during the time of preliminary drainage is decidedly the rule rather than the exception and is to be welcomed because of the immunity supposedly conferred. At any rate, high postoperative temperature reactions are relatively far more frequent among those who have not gone through a period of preoperative fever."

Under a program of interval catheterization the preoperative hospital sojourn of the patient is almost uniformly marked by a perfectly flat temperature chart, and epididymitis is rare. Since I am not an adherent of the "vaccination" theory, this

is accepted as further evidence of the superiority of interval catheterization over the retention catheter. The quoted statement of Davis conflicts not only with my personal experience but with the fact that vaccine therapy has been practically abandoned in the entire field of urology.

Although one might expect interval catheterization to entail a forbidding amount of routine drudgery in hospital wards, such has not been the case. A method has been adopted which combines speed, simplicity and irreproachable technic. Male nurses and intelligent orderlies with short coaching can execute the maneuver as well as a physician and better than the average intern, whose interest in some of the specialties is notoriously fitful.

The rapid method of catheterization is a no-touch technic, wherein the catheter is fed into the urethra with a sterile hemostat. Only the terminal two or three inches of the catheter is touched by fingers, and this portion does not enter the urethra. Hence gloves are unnecessary and the operator's hands need not be sterile, although I suggest that he wash them briefly with soap and water. A number 16 French coude olive-tip catheter has been found ideal as regards size and ease of entry: smaller catheters waste time, owing to slowness of flow; catheters with round tips are often arrested by the prostatic

Rapid no-touch technic of interval catheterization with No. 16 F. olive-tipped coude catheter. Limp old catheters are not suited to this method.

lobes. A quick dab of one of the newer mercurial antiseptics on the meatus is as effective a preparation for passage of the catheter as scrubbing with green soap, and much less traumatic.

With this "streamlined" technic a well trained orderly can accomplish catheterization of numerous prostatic patients with surprisingly little effort. It is only occasionally, when a very poor-risk patient requires several weeks of such preparation, that the repeated task tends to become onerous. Even then I feel that resulting benefits amply justify this method of preparation for surgery. In the very occasional case in which catheterization is so difficult as to require special methods (metal stylet) or where manipulation causes much bleeding, recourse is still had to the retention catheter. Postoperatively, of course, I use a retention catheter along with all my colleagues, the problem here being much different: temporary suspension of vesical function and control of bleeding by frequent irrigations have become the chief desiderata.

SUMMARY

A plea is made that interval catheterization replace the retention catheter in the treatment of patients being prepared for prostatic surgery. Such a change will minimize infection, promote the comfort of patients, facilitate the operative procedure, reduce operative hemorrhage and lessen postoperative reaction.

LIVER ABSCESS

R. WYNN MORRIS, M.D., HELENA, MONT.

A robust Austrian smelter worker had been complaining of digestive disturbance and pain in the epigastrium at various intervals for the past few months. Three weeks before admission to the hospital he was ill at home and in bed for four days with chills, fever, malaise and coughing, all symptoms of influenza. He recovered from this illness and returned to work

Fig. 1.—Graphic record of temperature.

for four days. He came home from work on the fifth day, sick again with chills and a temperature of 105 F. by mouth. He was immediately taken to the hospital, roentgenograms were made of the chest, and he was treated for pneumonia. Sulfapyridine was given on admission; the temperature dropped and the patient was nauseated, presumably from the sulfapyridine, but his general condition improved. Figure 1 shows the course of the illness until thirty-six hours before the end. He suffered from another severe chill and fever, and twelve hours before death he became deeply jaundiced; his temperature continued

Fig. 2.—Toothpick protruding from ventral surface of left lobe of liver.

to rise, and he died rather suddenly. He was conscious until a few moments before death.

The laboratory observations revealed no changes in the urine. The hemoglobin level was 14.3 Gm., 92.8 per cent, the red blood cell count was 4,510,000, and the white cell count on admission was 10,900; this was increased to 19,950 two days later.

A roentgenogram taken on the day of admission and the second plate, taken five days later, revealed no evidence of pulmonary congestion. Flat x-ray plates of the abdomen

revealed no evidence of the presence of gallstones or any other foreign bodies.

An autopsy was performed. There was no evidence of pulmonary congestion. The heart was normal in size and there was no defect in the valves. On exploration of the abdomen there was a mass in the epigastrium the size of a grapefruit, composed of adherent omentum, transverse colon, jejunum and the head of the pancreas. All of this mass was in turn firmly adherent to the left lobe of the liver. The liver was removed, and a toothpick was found protruding from the ventral surface

Fig. 3.—Ventral surface of liver, showing toothpick protruding from left lobe.

of the left lobe (figs. 2, 3 and 4). Dissection of the liver revealed a huge abscess, about 4 by 10 cm., across the ventral half of the left lobe. The toothpick passed directly into the encapsulated area of the abscess. The gallbladder was enlarged and inflamed, but no stones were found in the biliary tract. The stomach was extremely large, but there appeared to be no pathologic changes. The portion of the jejunum enclosed in the inflammatory mass was carefully dissected, but no evidence of the site of perforation by the toothpick through the bowel

Fig. 4.—Abscess of liver caused by foreign body (toothpick).

could be demonstrated. The pancreas was large, spongy and greatly congested. The other organs showed no great pathologic changes.

CONCLUSION

An interview with the family revealed that this corpulent man made a practice of lying down after dinner and falling sound asleep. Often he fell asleep with a toothpick in his mouth, and it is logical to assume that at some time during a nap he sighed deeply and aspirated the toothpick into his digestive tract. The wife stated that she never used toothpicks in sandwiches or cakes to hold them together.

SYMMETRICAL CORTICAL NECROSIS OF KIDNEYS

CARL HENRY DAVIS, M.D., WILMINGTON, DEL.

Symmetrical cortical necrosis of the kidneys as a puerperal complication was first reported by Bradford and Lawrence in 1898, and the paucity of cases described since their report makes it appear that this is a very rare complication. Most textbooks on obstetrics fail to mention this interesting and highly fatal condition. Approximately forty proved cases have been reported in the medical literature,¹ but as these have occurred in a relatively few clinics it is probable that many more fatal cases have been classified under toxemias of pregnancy. Hendry and Goodwin, while preparing a discussion of this subject for a chapter in Davis's *Gynecology and Obstetrics*, reviewed the fatal cases of "toxemia" at the Toronto General Hospital and located two of symmetrical cortical necrosis of the kidneys. The present brief report is made in the belief that familiarity with this type of lesion as a cause of anuria will lead to the discovery of many more cases. The case of puerperal symmetrical cortical necrosis of the kidneys to be reported here in detail has been mentioned by Hendry and Goodwin in their discussion as an unreported case.

REPORT OF CASE

History.—Mrs. B. Z., a Negro aged 24, married seven years, who had had no previous pregnancy, had her last period July 5, 1937. She registered at the outpatient department of St. Francis Hospital December 15. Her past medical history was negative except for the usual diseases of childhood. She had nausea and some vomiting during the early weeks of pregnancy. Her physical examination was negative: the blood pressure was 130 systolic, 80 diastolic, and the urine showed a faint trace of albumin and an occasional pus cell but no casts. Jan. 12, 1938, she complained of headache and dizzy spells; the blood pressure was still 130/80, she weighed 134 pounds (61 Kg.), and the urine still had a faint trace of albumin. January 25 she had a head cold and slight headache; the blood pressure was 116/70, she weighed 140½ pounds (64 Kg.), and there were a trace of albumin and many white blood cells in the urine but no casts. February 8 she had no complaints; the blood pressure was 120/70, her weight was 144 pounds (65 Kg.), and there were a trace of albumin and a few white blood cells but no casts in the urine. February 22 she had a slight head cold, the blood pressure was 116/70, her weight was 152 pounds (69 Kg.) and there were trace of albumin, a few white blood cells and no casts in the urine. March 8 a slight enlargement of the thyroid was noted, the blood pressure was 130/80, she weighed 152¾ pounds (69 Kg.), and there were a trace of albumin, a few white blood cells and no casts in the urine. March 22 she complained of vomiting and slight edema of the ankles; the blood pressure was 130/95, she weighed 154 pounds (70 Kg.) and the urine, which was examined after she left the hospital, showed a solid clot of albumin by the heat method. Unfortunately a laboratory technician recorded this finding without reporting it to the nurse in charge of the outpatient service. The patient walked into the hospital, apparently in active labor, on March 25, 1938. An hour later the nurse who was making the preparation reported more than normal bleeding and a diagnosis of ablatio placentae was made. No urine was obtained, but the blood pressure was 180/120. She was taken to the operating room and surgically prepared for examination. Vaginal examination showed a rigid, undilated cervix. She had a boardlike abdomen typical of ablatio placentae. Just before the gas was started she had a convulsion, her only one. The gas-ether anesthesia was started at 1:25 p. m. and ended at 1:55. When the abdomen was opened a fair amount of bloody fluid was found in the peritoneal cavity, and the uterine wall showed evidence of extensive hemorrhage. When the uterus was opened it was found that the placenta was completely separated and there was a large amount of blood clot within the uterus. After the dead fetus and placenta were removed the body of the uterus was removed, owing to the

1. For bibliography and photomicrographs see Gaspar, I. A.: *Bilateral Cortical Necrosis of Kidneys*, *Am. J. Clin. Path.* 8:281-301 (May) 1933.

extensive hemorrhage in the uterine muscle, both tubes and ovaries being left in. Following the operation the patient was given 50 cc. of 50 per cent dextrose intravenously, 1,000 cc. of physiologic solution of sodium chloride subcutaneously, and one-fourth grain (0.016 Gm.) of morphine hypodermically. At 5 o'clock her blood pressure was 105/80 and her condition seemed quite satisfactory. The next morning the patient complained that she could not see, and the eyegrounds were examined by Dr. Tybout, who noted that in the right eye the optic nerve disk was slightly congested but that the margins were well defined and there was no edema. The retinal veins were full and dilated but not engorged. The retinal arteries showed evidence of hypertension. Scattered throughout the retina were punctate dots of scattered gray infiltration with one large patch between the fovea and the margin of the optic disk. This would seem to indicate a subacute retinitis of one or two weeks' standing. The vision was not taken. The same conditions were present in the left eye as in the right eye with the exception that points of infiltration throughout the retina were much more scattered and smaller. The sudden total blindness was regarded as due to some undetermined central disturbance along the course of the optic tract.

There was an almost complete suppression of urine during the patient's entire postoperative course, notwithstanding attempts to stimulate the kidney function through the use of 50 per cent dextrose solution intravenously, hot packs and warm irrigations of the bladder. The type of operation ruled out the possibility that the ureters might be ligated, and a disorder of the glomeruli was considered the probable cause of the anuria. Not more than 2 ounces (60 cc.) of urine was obtained during a period of twenty-four hours. There was a slight elevation of temperature during the day following the operation, and on March 27 it remained above 100 F. all day, reaching 100.8 F. at 4 and 8 p. m. The next day the temperature dropped to 98 F. and remained slightly subnormal until the time of her death at 6 a. m. April 5. Her postoperative pulse varied from 70 to 90 until just before death, when it went up to 120. A partial autopsy was performed by Dr. D. M. Gay at 9 o'clock, three hours after death.

Necropsy.—The lower midline abdominal incision, 12.5 cm. long, showed normal processes of healing. There was no evidence of infection of the wound. Grossly, the heart, pancreas, liver, gastrointestinal tract and genital organs showed no deviation from normal. The surfaces of the peritoneal cavity were smooth and glistening except in the pelvis, where a few young fibrous adhesions united the omentum with the stump of the uterus which was removed at operation. A few cubic centimeters of thin clear yellow fluid was present. The spleen was about twice normal size and its capsule was thin over a smooth dark purple surface. On section the splenic substance was soft in consistency and could be easily scraped away. The kidneys were similar and of approximately normal size. The capsule stripped spontaneously from a smooth, remarkably pale light brown surface. On section the cortex was a similar light gray brown, sharply demarcated from the kidney medulla, which was of approximately normal color. The calices and pelvis were normal; the ureters were slightly dilated.

Microscopic examination of sections of the pancreas gave negative results. There was a moderate degree of congestion of the spleen, and the pulp cells were abundant with a few local groups of plasma cells. In general the histologic picture of the liver appeared normal. However, there was evidence of reaction to injury in the vicinity of the portal spaces, characterized by slight variation in size and staining intensity of the liver cell nuclei and occasional mitotic figures. None of the cells appeared necrotic and there was no cellular infiltration. In the kidneys these striking cortical changes were infarcts due to occlusion of the small branches of the renal artery by organizing thrombi. The infarcted portion extended from the medulla to the capsule, with the frequent exception of a narrow subcapsular zone of living tissue nourished by capsular vessels. Tubular and glomerular formation could be made out but all cellular detail was lost. Nuclear fragments were scattered through the bright red staining necrotic cytoplasm. The arteries were occluded by masses of old red staining fibrin, which was

frequently almost entirely replaced by young fibroblasts growing from the subendothelial tissue. Many of the collecting tubules were filled with plugs of albuminous material.

The anatomic diagnosis was symmetrical cortical necrosis of the kidneys and postpartum state.

COMMENT

A review of the various cases reported in the literature indicates that the clinical background of nearly all cases proved symmetrical cortical necrosis of the kidneys was suggestive of preeclampsia or a nephritic toxemia. More often the toxemic picture developed shortly before the onset of labor. Thus far there are no characteristic symptoms or manifestations which enable one to predict the development of symmetrical cortical necrosis. Premature delivery of a fetus, dead and frequently macerated, usually followed at once by anuria, has been the rule. However, Jardine in 1910 delivered a toxic woman of live twin girls, weighing 4 and 4½ pounds (1,814 and 2,040 Gm.) respectively; subsequently anuria developed and the patient died in convulsions two and a half days later. She had extensive liver damage as well as symmetrical cortical necrosis. In at least one third of the reported cases there was evidence of retroplacental hemorrhage or ablatio placentae. Incomplete information, as in our case, makes it impossible to state whether or not anuria preceded the death of the fetus.

Curiously, these patients exhibit few if any of the classic uremic symptoms, the clinical picture associated with the suppression resembling more closely that associated with bilateral ureteral obstruction. Progressive retention of nitrogen in the blood is commonly reported.

It has been assumed, since the diagnosis is usually based on an autopsy report, that symmetrical cortical necrosis of the kidneys is a fatal condition, but there is apparently one authentic case in which recovery occurred following decapsulation. Arthur Crook in 1927 reported a case of postpartum anuria in which recovery followed decapsulation of the kidney. A portion of the renal substance removed at the time of the operation showed necrosis of the glomeruli and tubules and engorgement of the glomerular capillaries and tubules and smaller vessels of the cortex. It is fortunate that there is Crook's microscopic evidence of necrosis in a case in which recovery occurred, since it indicates that some degree of cortical necrosis may occur in cases in which there is a period of anuria without sufficient involvement to cause death. Arnott and Keller (1933) reported a case of anuria caused by cortical necrosis in which the patient lived thirty-two days, and they describe signs of progressive improvement shortly before the patient died. Gibberd (1936) reported that a woman lived with some evidence of improvement for twenty days, eventually dying, he believes, from her profound anemia; the pathologic manifestations were typical. Within two years Gibberd observed two other patients clinically diagnosed as having cortical necrosis, who recovered under medical management. He is of the opinion that symmetrical cortical necrosis may not be such an uncommon condition, believing that for every fatal case there may be a number with a less extensive and therefore nonfatal involvement. I have already stated that in my patient, who lived eleven days, there was microscopic evidence of a healing process in the kidney substance. The medical management was quite similar to that suggested by Gibberd.

A review of the cases reported in the literature indicates a general failure to describe the condition of the adrenals. Unfortunately we do not have the adrenals from the case described in this paper. Jardine and Teacher in their paper (1911) give the following description of the microscopic appearance of the adrenal in one of the cases reported:

"The suprarenal showed pronounced cloudy swelling affecting both cortex and medulla. There were also patches in which the cells were separated from one another as if in an early stage of necrosis, and there were a few areas in which they were quite definitely necrotic. These were seen both in the cortex and in the medulla. They were very small. The blood vessels were intensely gorged with blood, but no definite thrombosis was found, and the little patches of necrosis did not suggest infarction." It is interesting to note that grossly "the supra-

renal bodies appeared to be normal." Gaspar in his paper (1938) says of the pancreas and adrenals "moderate passive congestion."

A review of the cases of symmetrical cortical necrosis of the kidney reported in the literature and a careful study of all data available in the case herewith reported suggests that the kidney condition is a pathologic manifestation of an extremely severe toxemia of pregnancy. Many of the women who died after varying periods of anuria had convulsions. With few exceptions the women who have died from this condition had some evidence of a more or less severe toxemia of pregnancy before the intra-uterine death of the fetus. The case reported in 1926 by J. C. Hirst furnishes a notable exception, as the blood pressure was normal and the urine contained neither albumin nor casts when the patient was admitted to the hospital two days after an easy spontaneous delivery of a badly macerated seven and one-half months fetus. The toxin, whatever its nature, must be extremely potent, since it has killed practically all the infants in utero in addition to causing extensive damage to both kidneys and lesser degrees of damage to other vital organs. While liver damage is commonly described, it is not typical of that expected in a case of fatal eclampsia. Nevertheless, it would seem that this condition should be classified under toxemia of pregnancy, possibly as an atypical variety of eclampsia.

A sudden abnormal increase in weight is the most common early sign of impending toxemia. It will be noted that in the case reported in this paper there was a gain of 8 pounds (3.6 Kg.) between February 8 and February 22, without an increase in blood pressure or change from the usual slight trace of albumin. The severe toxemia was not apparent until four weeks later. My experience indicates that all patients who show any such sudden increases in weight should have bed rest, elimination of sodium salts, restriction of fluids to a normal intake and adequate catharsis. This type of treatment enables one to control most cases of impending toxemia. Such treatment might have saved this patient if it had been instituted in February.

Medical Arts Building.

SOLUTION OF GALLSTONES

C. M. BURGESS, M.D., HONOLULU, T. H.

Generally speaking, surgery of no other portion of the human body requires such fineness of judgment and care in execution as does that of the biliary tract. Especially is this true in those cases (and they are seen frequently) in which there has been a previous cholecystectomy or cholecystotomy and then the clinical manifestations of obstruction of the common duct appear. It is these cases that tax the surgeon's skill, both because of the technical problem involved and because they are seldom even fair risks.

Any effective substitute procedure, even though it is applicable to an exceedingly small group of these cases, is most welcome. In order to dissolve a stone from the common duct it is plain that certain definite conditions must be present. The stone must be situated so that it may be bathed directly with the solvent used—so that either a tube drain must be placed in the common duct or there must be a biliary fistula. Secondly, the stone must be soluble. This implies that it must be either pure cholesterol or formed of small fragments bound together by cholesterol. The fact that few stones fall in this group greatly limits the use of this procedure. If the stone is of the type in which cholesterol is only the binding agent and the solvent merely fragments it, there must be a sphincter capable of responding to drugs—that is, it must dilate at the proper time. That a normal sphincter will respond to drugs has been definitely shown both by animal and by human experimentation. Morphine is one that contracts the sphincter while amyl nitrite or glyceryl trinitrate causes relaxation. Also the procedure must be carried out with care. Ether seems

the most favorable agent but it volatilizes at body temperature, and it is conceivable that pressure so generated may be of such force as to cause damage to the delicate biliary tree. However, this can be recognized by the operator, since dilatation gives rise to pain and discomfort to the patient. A certain limited amount of positive pressure is thought to be desirable in this procedure.

Fig. 1.—Tracing of roentgenogram showing that opaque medium does not pass ampulla. Biliary tree is well outlined.

Such a case was recently seen at the Clinic:

J. B. L., a man aged 42, a Caucasian, was seen in 1934 with what appeared to be an attack of gallstone colic. It was characterized by flatulence and epigastric pain of sudden onset and intermittent type, accompanied by nausea and vomiting. He had had several such attacks during the previous two years but of milder nature. The pain had no relation to meals and was not relieved by sodium bicarbonate. Physical examination showed slight tenderness over the gallbladder and little else. A gallbladder series at that time showed very poor function, and suspicious shadows were interpreted as being stones. Cholecystectomy was advised but was refused. The attack subsided and the patient had no symptoms referable to the gallbladder until Feb. 5, 1938, four years later.

The symptoms on February 5 were similar to those in previous attacks but more severe and were accompanied by fever, leukocytosis and more marked local manifestations. The patient was treated symptomatically at home for a day against the advice of his physician, but on the second day the symptoms and signs grew more alarming and he consented to hospitali-

Fig. 2.—Tracing of roentgenogram taken after two injections of ether, showing some diodast in the duodenum. Also shadow which might be a stone near the ampulla. Biliary tree is faintly demonstrated.

zation. On the third day an emergency operation was done. His condition was only fair; he was very toxemic, the temperature was 101 F. and the white blood count was 21,000, with a high polymorphonuclear count.

At operation an empyema of the gallbladder was found. Because of the acute and extensive involvement and because

of the patient's poor condition, only the removal of all readily available stones plus a cholecystotomy were done. Convalescence was very smooth and the patient was discharged with a draining biliary fistula on the tenth hospital day.

The drainage became less and a week later it ceased. This was followed by general malaise, fever, nausea and epigastric pain. A stone in the common duct was suspected and on March 1 almost complete obstruction at the ampulla was demonstrated by injection of diodrast into the fistula (fig. 1). Some of the stones removed at operation were placed in ether and found to dissolve almost immediately. Others became fragmented into fine particles that appeared to be organic.

The technical difficulty of exploring the common duct after the severity of this inflammatory process was considerable. All conditions for attempted solution of the stones seemed favorable, so it was decided to try the method described by Pribram¹ in 1935 and more recently by Walters and Wesson,² of the Mayo Clinic. On March 2, nearly a month from the date of the operation, 5 cc. of ether was injected into the fistula and the patient was given $\frac{1}{100}$ grain (0.6 mg.) of glyceryl trinitrate by mouth. A no. 12 catheter and a 10 cc. Luer syringe were used for the injection, which was done with care; at the first indication of pain the tube was released. Ether could be noted in the breath almost immediately. Following this there was a moderate reaction, consisting of belching and epigastric pain. As soon as this distress subsided, 2.5 cc. more of ether was injected, 7.5 cc. in all being given. Considerable discomfort continued throughout the night, but the drainage from the tract seemed less.

March 3 the injection of ether was repeated and the patient at the same time inhaled an amyl nitrite pearl. March 4 the patient felt so poorly and so much bile was draining that

Fig. 3.—Tracing of roentgenogram showing functioning ampulla with no dye in the finer radicles.

no injection was done. At this time the stool was reported negative for bile.

March 7 (five days after first injection of ether) another diodrast injection of the tract was made which showed a considerable amount, perhaps 10 per cent, of the opaque solution passing into the duodenum (fig. 2). He received another injection of 5 cc. of ether on March 8, and 10 cc. was injected again on March 9, the patient inhaling a pearl of amyl nitrite each time. The last two injections gave rise to only slight reactions.

On March 11 an injection of diodrast showed a normal functioning duct and ampulla (fig. 3). The catheter drain was removed from the tract and prompt healing ensued. The patient has had no symptoms referable to the biliary tract to date, a period of twenty-three months.

2. Walters, Waltmann, and Wesson, H. R.: Fragmentation and Expulsion of a Common Duct Stone into the Duodenum Using Ether and Amyl Nitrite: Preliminary Report, *Proc. Staff Meet., Mayo Clin.* 12: 260 (April 28) 1937.

SUMMARY

The case here presented is instructive and interesting from several points of view: First, it brings up again the time proved fact that stones in the gallbladder, although they may lie symptomless for years, may ultimately give rise to disease and, as in this case, seriously threaten the life of the patient. Second, it emphasizes the value of visualizing the biliary tract in cases presenting either drainage of the common duct or a persistent fistula. This is a harmless procedure which gives information that cannot be had in any other way. Third, it definitely shows that certain stones can be dissolved or at least fragmented so that they will pass the sphincter, though this solubility is unfortunately not a characteristic of gallstones in general. The knowledge that certain stones are soluble if they are available to a direct bath in ether is a real addition to our armamentarium of treatment in these constantly serious technical problems of common duct stones.

The injection of ether into the biliary tract to dissolve gallstones at first consideration appears to be a heroic measure. However, it has been done in enough instances to make one feel safe in its use when done properly. It is plain that this therapeutic measure can be applied in only a limited number of cases.

SUBACUTE BACTERIAL ENDOCARDITIS SUCCESSFULLY TREATED WITH SULFANILAMIDE

REPORT OF WELL ESTABLISHED CASE EIGHTEEN MONTHS AFTER RECOVERY

JACOB HEYMAN, M.D., NEWARK, N. J.

This case of subacute bacterial endocarditis is presented as one in which the most rigid criteria of diagnosis and recovery have been observed. The important feature was the treatment with small doses of sulfanilamide over a long period. The value of small doses has been demonstrated by Ellis¹ in a report of two cases treated with sulfapyridine. Unfortunate circumstances interrupted the treatment, however, and eventually both patients died. Spink and Crago² observed the lack of a definite relationship between the amount of sulfanilamide in the blood and its effect on the bacteremia. In one of their cases under treatment the blood was rendered sterile at as low a level as 3.1 mg. of sulfanilamide per hundred cubic centimeters of blood.

In view of the fact that the disease is almost invariably fatal, and since attempts at specific therapy have thus far proved discouraging,³ a detailed description of this case seems warranted.

REPORT OF CASE

Mrs. G. B., aged 38, seen in my office Jan. 30, 1938, complaining of headaches, malaise and sweats, had a questionable history of rheumatic fever in childhood, but heart disease was said to have been discovered when the patient was 2 years old. Having treated her for a minor ailment in September 1937, I was aware of the presence of a patent ductus arteriosus.

On examination the patient weighed 105 pounds (47.6 Kg.) and was 4 feet 9 inches (145 cm.) tall. The heart was enlarged to percussion and the apex beat was palpably displaced downward and to the left.⁴ There was a murmur over the pulmonic area heard in systole and diastole and a harsh, blowing apical systolic murmur transmitted to the axilla. The temperature was 100 F. and the pulse 100 and regular.

2. Spink, W. W., and Crago, F. H.: Evaluation of Sulfanilamide in the Treatment of Patients with Subacute Bacterial Endocarditis, *Arch. Int. Med.* 64: 228 (Aug.) 1939.

3. In a recent article Kelson and White (A New Method of Treatment of Subacute Bacterial Endocarditis, *J. A. M. A.* 113: 1700 [Nov. 4] 1939) report the combined use of sulfapyridine and heparin in a series of six cases of which three were symptom free for nineteen weeks, eighteen weeks, and four weeks respectively. Although this was a preliminary report, the results seem promising. Since heparin was used in this series, it does not come within the scope of the present article.

4. Recent x-ray films taken in February 1940 revealed the type of heart shadow usually seen in patent ductus arteriosus. The esophogram in the right oblique view showed a normal left auricle.

Despite the absence of joint symptoms, rheumatic fever was suspected, and accordingly the patient was advised to remain in bed. For the following week or two the headaches, fever and tachycardia continued and the sweats gradually increased in severity and were accompanied by chills. The temperature varied from 100 to 102 F. and the pulse from 100 to 120. There were no petechiae and no discernible embolic phenomena, but the patient appeared increasingly septic. Bacterial endocarditis was suspected and hospitalization was advised. The patient rejected the suggestion but later entered the Hospital of St. Barnabas⁵ in the service of Dr. W. D. Miningham, remaining there from March 1 to April 22, 1938.

During her stay in the hospital her temperature was irregular, ranging from 101.5 to 104.6 F. Her pulse varied from 98 to 130 and on one occasion dropped to 50 for a brief period. On admission the hemoglobin reading was 74 per cent and erythrocytes numbered 4,080,000 per cubic millimeter. The leukocyte count was 9,800 with 80 per cent polymorphonuclear cells. The urine was normal except for the presence of 4 or 5 erythrocytes per high power field. A blood culture taken on March 2 showed 86 colonies of *Streptococcus viridans* per cubic centimeter of blood on March 5. Another taken on March 14 showed 35 colonies of *Streptococcus viridans* per cubic centimeter on March 17.

While in the hospital her condition became progressively worse. The headaches increased in intensity and she was almost constantly fatigued and listless. On March 21 a dry unproductive cough developed which persisted for weeks after her discharge. On March 27 the patient experienced a severe shaking chill which lasted thirty minutes. On April 1 she suffered a sudden, severe pain in the right side of the chest, accompanied by a chill which lasted for an hour. During this period she began to complain of pains, at times generalized but usually in the thoracic region, accompanied by dyspnea. In the latter half of her hospital stay the pain became so severe that she often required three or four hypodermic injections of morphine sulfate or dilaudid hydrochloride daily for relief. From March 6 to April 2 the patient received five blood transfusions in addition to the usual supportive measures. She was discharged in "critical condition" against advice on April 22 and left the hospital by ambulance.

Within a short time after her discharge I was recalled as her attending physician. At this time she was considerably emaciated (her exact weight in June was 63 pounds [28.6 Kg.]), and extremely pale and toxic. The temperature was 104 F., the pulse was rapid and irregular and the chills and sweats were more disturbing. Pains in the chest continued to be severe, occurring in the upper anterior part of the chest, left or right, and at either base posteriorly. A smothering type of dyspnea accompanied the pain, particularly when it was localized over the precordium. Cardiac action had now become more violent, fibrillation occurred frequently and the murmurs became coarser and were accompanied by thrills. There was no evidence of petechiae, although during the ensuing few months there was clinical evidence on one occasion of a splenic infarct and on other occasions of minor pulmonary emboli. The latter were always associated with pain in the chest and severe shaking chills lasting thirty minutes or longer.

In the early part of May treatment with sulfanilamide was started. The patient received 60 grains (4 Gm.) on the first day, 40 grains (2.6 Gm.) daily for the next two days and approximately 20 to 30 grains (1.3 to 2 Gm.) daily for three months. It was not possible to obtain blood counts and blood sulfanilamide determinations; hence it was necessary to rely solely on clinical observations. The patient tolerated sulfanilamide very well, however, and at no time was there jaundice or cyanosis. The only toxic symptoms noted were anorexia and periodic vomiting, which on two or three occasions necessitated discontinuance of the drug for a period of one day. The temperature and pulse gradually fell shortly after the institution of sulfanilamide therapy, although there was no sudden, dramatic decline. Fever, chills, sweats, headache, chest pains and dyspnea continued with gradually lessening severity

until late in August. The patient was now less septic, the temperature remained nearer normal and the disease appeared more benign. The dosage was decreased and the patient received no more than from 15 to 20 grains (1 to 1.3 Gm.) daily.

In October there was considerable subjective improvement and the temperature was normal except for an infrequent slight elevation. Sulfanilamide was discontinued and the patient began to get out of bed for short periods. Two weeks later there was a rise in temperature to 100.5 F. and a recurrence of subjective complaints. She was ordered back to bed, following which the temperature and symptoms subsided promptly.

By the end of November the temperature was normal, the pulse varied between 96 and 100 (the pulse was rapid prior to illness) and chills and sweats had completely disappeared. She was allowed out of bed and sulfanilamide was permanently discontinued. From that time (November 1938) to the present (May 1940) there has been no evidence of fever. (The patient had been instructed to take her temperature once or twice a day during that period.) Her appetite had improved, her weight was increasing and she rapidly resumed her normal routine of living. She has, furthermore, shown none of the characteristics of "bacteria-free"⁶ cases. Clinically, therefore, her recovery may be dated from November 1938, a period of eighteen months. Although she was well in October, there was a slight rise in temperature for a short period during that month.

The patient was last examined Feb. 11, 1940. Her weight at that time was 109 pounds (49.4 Kg.), and her pulse was 92, regular and of good quality. The mitral systolic murmur at the apex was no longer audible, while the murmur over the pulmonic area due to the patent ductus arteriosus was still present. The spleen was not palpable.

On Oct. 14, 1939, eleven months after clinical recovery, blood studies were undertaken at the laboratories of the Newark Beth Israel Hospital through the courtesy of Dr. William Antopol. A blood culture taken and examined by Dr. Philip Levine was sterile after three weeks' incubation; the hemoglobin reading was 92 per cent and the erythrocyte count 4,720,000. The leukocyte count and smear were normal. The sedimentation rate was 25 mm. after one hour and 45 mm. after two hours. Another blood culture taken on November 7 remained sterile after three weeks, and a third taken on Feb. 7, 1940, was likewise sterile. Examinations of the urine have been repeatedly negative.

COMMENT

Dr. Emanuel Libman became interested in this patient and examined her on Oct. 12, 1939, and again on Nov. 13, 1939, expressing the opinion that the case represented an authentic cure. He called my attention to an unusual type of erythema on the volar aspects of both hands and the soles of both feet. The eruption had been more pronounced at the height of her illness, involving the palmar surfaces of both hands in a vivid symmetrical erythema sparing only the center of the palms, with a similar eruption on the soles of the feet. It has since faded considerably and now involves mainly the thenar and hypothenar eminences and volar aspects of the distal parts of the fingers. On the feet, only the outer aspects of the soles are affected. There is no reference to this lesion in the literature, although it was described by Dr. Libman in 1928.⁷

Dr. Libman has contributed some interesting comments in reference to the rash noted in this case. Referring to his lecture at the New York Post-Graduate Hospital, he writes⁸ as follows concerning this case:

"I spoke then of occasionally observing in cases of subacute bacterial endocarditis a 'brilliantly colored erythema of the palms of the hands and the soles of the feet.' Of course, one sees milder grades of this lesion under other conditions and therefore must be careful in evaluating it for diagnostic purposes. In your case the erythema was still quite marked when I saw the patient for the first time. I imagine that it was more intense during the active stage.

6. The term "bacteria-free" is used by Emanuel Libman (A Consideration of the Prognosis in Subacute Bacterial Endocarditis, *Am. Heart J.* 1: 25 [Oct.] 1925) in referring to those patients who have lost the infection but in whom residua or sequelae are clinically manifest.

7. From the unpublished records of a lecture on endocarditis delivered by Libman at the New York Post-Graduate Hospital, October 12, 1928.

8. Libman, Emanuel: Personal communication to the author.

5. Hospital records were obtained through Dr. Miningham.

"Occasionally this erythema puts one on the track of the diagnosis in subacute bacterial endocarditis. In my experience it is located in the same areas in which one usually finds the Osler lesions."

Although remissions of varying degree occur in subacute bacterial endocarditis, a review of the case here reported would serve to demonstrate that this represents a cure rather than a remission. The striking change in a septic patient weighing 63 pounds, who now weighs 109 pounds and has been free from symptoms and fever for over a year, speaks against the possibility of a remission. Added to this are negative blood cultures, a hemoglobin reading of 92 per cent and an essentially normal, if slightly elevated, sedimentation rate. Since cases of spontaneous recovery have been reported, the question arises whether this patient would have recovered spontaneously without treatment. Dr. Libman has reported four such recoveries in his first series of 150 cases, or 3 per cent, in the form of the disease to which this case corresponds, namely "cases of usual type." The favorable response of this patient to sulfanilamide may have been merely coincidental. Yet, if this is attributed to coincidence, it still leaves unexplained the recurrence of fever and symptoms when sulfanilamide was discontinued in October 1938 and their disappearance when therapy was resumed.

It must be emphasized that the patient was given unusually small doses. Our concept of sulfanilamide therapy has been based on its early use in acute diseases with a relatively short and stormy course, and it has been natural to think of the drug in terms of large, so-called effective dosage. In a more chronic disease, such as subacute bacterial endocarditis, which requires prolonged therapy, it is reasonable to assume that smaller doses would seem preferable. Cases have been reported, notably one by Major and Leger,⁹ in which large doses in spite of obvious effectiveness did not influence the final outcome of this disease.¹⁰ Massive doses may perhaps be of value in cases of early involvement. However, when thickened vegetations exist supplying sustenance to ever increasing colonies of bacteria, it is difficult to conceive how a short intensive treatment could effect a permanent cure.

Qualified observers have expressed discouragement over the use of sulfanilamide in subacute bacterial endocarditis. Such extreme pessimism seems premature, since the possible schemes of therapy with this group of chemicals have not all been exhausted.

In this case small doses were used for the following reasons:

1. Dealing with a protracted disease, I felt that the dosage should be so apportioned that sulfanilamide could be administered throughout the whole course of the disease. Were I to have employed so-called standard dosage, it might have been necessary to discontinue the drug after three or four weeks.
2. The patient required less than the average dose because of her weight. The dose given might have been considered normal except for the fact that she received as little as 15 grains daily in October 1938 after she had gained at least 20 pounds (9 Kg.).
3. Without the benefit of laboratory aid, the risk of erring on the side of underdosage rather than overdosage was deemed more advisable.

SUMMARY AND CONCLUSIONS

1. In the case of subacute bacterial endocarditis here reported, positive blood cultures established the diagnosis. In this case small doses of sulfanilamide were given over a period of six months.
2. It is felt that small dosage maintained over a long period of time merits consideration in the treatment of this disease.
3. The treatment of subacute bacterial endocarditis with sulfanilamide or its derivatives should not be hastily abandoned if results are not immediate; on the contrary, it should be continued persistently so long as the drug is tolerated.

CONFERENCES ON THERAPY

THE TREATMENT OF BLOOD DISORDERS

III. THE USE OF TRANSFUSIONS

NOTE.—These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with the collaboration of other departments. The questions and discussions involve participation by members of the staff of the college and hospital, students and visitors. The next report will concern "The Treatment of Blood Disorders: IV. Roentgen Therapy."

DR. EUGENE F. DU BOIS: Today we continue the subject of the treatment of blood disorders and discuss the use of transfusions. Dr. Forkner will talk on the clinical aspects.

CLINICAL ASPECTS OF TRANSFUSIONS

DR. CLAUDE E. FORKNER: Transfusion, as you know, has been recommended for the treatment of almost every disease. There has been a great deal of enthusiasm at certain periods in the history of transfusion for this procedure, and at other times it has fallen into disrepute. Particularly since the last war transfusion has been used very widely throughout the world, and this might be said to be a period of enthusiasm for transfusion.

Previously the untoward effects from transfusions caused this procedure to fall into disrepute, but largely as a result of the application of newer knowledge and of newer technics these untoward reactions have been eliminated, so there have been relatively few times when transfusion has been felt to be contraindicated.

The indications for transfusions in diseases of the blood are not many. Perhaps the best way to discuss this is to take up the various disorders of the blood more or less in order. We might consider first anemia due to hemorrhage. If the anemia is recent and very severe, it may be necessary for transfusion to be given immediately in order to sustain life. In that event a transfusion may be necessary at a much higher level of the red blood cells and of hemoglobin than when anemia develops slowly because the individual accommodates himself to a low hemoglobin and a low red cell count when the process is gradual, whereas he goes into shock if he loses a large amount of blood suddenly. After acute, severe hemorrhage, even though the red blood cell count may be normal or only moderately reduced, it is often necessary to give a transfusion immediately.

There is one possible exception and that is the giving of blood to a patient who has suffered from a recent hemorrhage from a peptic ulcer. Under those circumstances it is generally believed that transfusion is actually dangerous and wasteful. The usual procedure is to avoid giving a transfusion to a patient who is bleeding actively from a peptic ulcer and to wait until bleeding has stopped for a period of time. However, under those circumstances one must be extremely cautious and not allow the patient to drift into severe shock. Good results are not to be expected from a transfusion during the course of severe bleeding from a peptic ulcer, but it may be practically the only thing that one can do in an attempt to combat shock in exsanguination.

Transfusions are used very widely in surgical practice, and often I think without good reason. As a rule transfusion in surgical cases is indicated for anemia of the grade which produces symptoms or as a preoperative procedure in anticipation of possible shock or loss of excessive amounts of blood. I think that transfusions given as a general tonic to surgical patients are usually unjustified and many more of them are given in most hospitals than are really indicated.

Infections, particularly those which are apt to produce anemia rapidly, frequently are benefited by transfusion. Especially is that true with the hemolytic streptococcus infections such as scarlet fever of a virulent type. In those instances I think transfusions are very useful, but as a rule in infectious diseases transfusions accomplish little, and the detailed studies that have been made by a large number of workers indicate that no better results are obtained by transfusions in ordinary infectious diseases than when transfusions are omitted. I think this is perhaps somewhat contrary to the point of view of the pediatricians, and I should be glad to hear from Dr. Smith on that.

As a rule in an anemia which is not developing rapidly one does not need to give a patient a transfusion before his red blood cells reach a level of 2,000,000 or thereabouts and before his hemoglobin reaches a level of about 5 or 6 Gm. At that time patients who are up and about begin to have symptoms of anemia. Those symptoms are palpitation and generalized discomfort, and there are signs of anoxemia. Under these circumstances I think that transfusion should be given to hasten recovery or prevent serious symptoms from developing. If a patient has a hemoglobin value below 4 Gm. or if his red blood cells drop below 1,500,000, one can anticipate that that individual is near the breaking point. If the hemoglobin or red blood cells go slightly lower, there may be sudden decompensation of the heart or other severe symptoms which then cannot be remedied easily; so one must watch such patients carefully and not hesitate too long about giving transfusions. On the other hand I think that anemia alone, let us say around 3,000,000 red cells or around 8 Gm. of hemoglobin, is not per se an indication for the transfusion of blood.

In pernicious anemia prior to 1926 transfusion was about the only method that we had of restoring the blood during periods of relapse, but more recently, since the advent of treatment with liver or liver extract, it has rarely been necessary to employ transfusion in a case of pernicious anemia and it is the opinion of most workers that patients are better off if they do not receive transfusions but are allowed to regenerate their own hemoglobin and their own red cells as a result of adequate treatment. However, if a patient with pernicious anemia first presents himself with an acute relapse, if he has a dilated heart or if he has symptoms of anoxemia, one must not hesitate to administer transfusions to tide over the period before liver extract makes itself felt.

The anemias of pregnancy rarely require transfusion and usually respond fairly well to therapeutic agents, depending on whether the anemia is of the microcytic type or the macrocytic type; that is, the macrocytic types respond to doses of liver extract or to the administration of adequate amounts of the vitamin B complex, and the microcytic types of anemia respond to treatment with iron.

Banti's disease and cirrhosis of the liver sometimes are associated with very severe anemia, and in those

diseases I think it is well to give at least a few transfusions because frequently the livers of such patients tend to regenerate, and sometimes they have a year or two or even more of active life thereafter, if one can protect them during the period of severe anemia.

Aplastic anemia and that whole group of poorly understood refractory anemias, at least refractory for a time, are best treated by means of transfusions, with the hope that one can tide these patients over the period in which the deleterious effects of whatever toxin has exerted its effects on the bone marrow may be spontaneously overcome. That is particularly true in the so-called secondary aplastic anemias, those due to benzene poisoning or to poisoning with other drugs and perhaps to effects of too severe irradiation with x-rays or with radium. Frequently it happens, however, that in true aplastic anemia transfusions are only palliative and eventually the patient succumbs to the disease. It is well worth keeping him alive for a period of several weeks or several months by repeated transfusions in the hope that he will recover spontaneously.

In the disease known as erythroblastic anemia or Cooley's anemia, transfusions are sometimes indicated when the anemia is severe. They may prolong the life of the patient for a period of time, but too much must not be expected from transfusions in that disease.

Erythroblastosis of the newborn requires immediate transfusion, and this is often a lifesaving procedure; hemorrhagic disease of the newborn also comes in that category.

Hemophilia and a number of other related diseases, so-called pseudohemophilia, constitutional thrombopathy and hereditary thrombasthenia are all benefited markedly by transfusions, and often the bleeding can be controlled by frequent small transfusions. In these disorders transfusions often are necessary before and after surgical operations, tooth extractions and the like. By giving a transfusion before the procedure and about every second day thereafter, one can usually control the hemorrhage so that operations are done with less danger.

The purpuric diseases, particularly idiopathic purpura haemorrhagica, are best treated by transfusion in an attempt to tide the patient over his attack and get him to a place where other procedures, notably splenectomy, can be carried out. It often happens in purpura haemorrhagica that the number of platelets is increased after transfusion, and sometimes they are increased beyond the expected amount of increase from the transfused blood; in other words, there seems to be some reaction in the recipient which favors the development of new thrombocytes.

The hemorrhagic manifestations of obstructive jaundice were formerly treated fairly effectively preoperatively by transfusions, but in more recent times vitamin K together with bile salts have largely been substituted for transfusions in this disorder, although if the hemorrhage is marked transfusions still have their place.

Leukemia is a disease in which transfusion often is practiced, although it is debatable whether or not one should use this method of treatment. Transfusions undoubtedly may prolong for a few days or weeks the life of patients who have acute leukemia. Usually the effect is fleeting. I think that a good rule to follow in that instance is that if one is not absolutely sure of the diagnosis of acute leukemia—and that frequently is true—one should resort to transfusions in the hope that one is dealing with a leukemoid or leukemia-like condition which may be susceptible of cure; but after one

is convinced that real leukemia is present then I think it is futile and unnecessary to continue transfusions of blood.

In the chronic leukemias, transfusions rarely are indicated. When a chronic leukemic patient gets a low red cell and hemoglobin level, particularly in chronic lymphogenous leukemia, he may be given transfusions and perhaps made better for a time, but a permanent effect cannot be expected. There are, of course, exceptions to this rule, and one should say in general that each patient should be considered individually. No hard and fast general rules can be made about transfusions in any of these disorders.

Granulocytopenia is a disease in which transfusion is frequently advocated and frequently given, but I think there is no support in the literature or in my own experience for the belief that transfusions are of value in the disease called agranulocytic angina. Our own studies on a group of ten patients with severe leukopenia, several of whom had acute agranulocytosis, showed that the white blood cells, counted every fifteen minutes immediately before, during and for several hours after the transfusion of 500 cc. of blood, within an hour or so often were lower than was the case before the transfusions were started, and that there was no permanent benefit or lasting increase of white blood cells in the recipient. Apparently the transfused leukocytes are all taken out of the circulation very quickly.

Sometimes one considers transfusion of blood in patients with lymphoblastoma—and I use that term rather generally to include lymphosarcoma and reticulum cell sarcoma and perhaps Hodgkin's disease. I think that when a patient's blood reaches a level requiring transfusions in those diseases one can expect little from transfusion. Sometimes transfusions will hasten a temporary recovery when they are given in conjunction with other effective treatment.

Methemoglobinemia may be an indication for transfusion when it is marked and when the patient suffers as a result of anoxemia.

Carbon monoxide poisoning may be another indication for transfusion in order to supply more red blood cells which can function in their capacity as carriers of oxygen and carbon dioxide.

I should like to say that there are two contraindications for the use of transfusion in the treatment of diseases of the blood: One is pulmonary edema; another is cardiac decompensation or known severe myocardial damage. Under those circumstances if one is forced to treat with transfusion it must be given slowly, but it is better to avoid it under those circumstances because the circulation may be overburdened. On the other hand, it frequently happens that if an anemic patient has myocardial failure as a result of anoxemia a transfusion will actually reduce the myocardial failure by lessening the burden on the heart.

I think a general rule in all diseases that require transfusion is to say Don't give a transfusion unless you have to; if you have to, it may be a lifesaving procedure.

PHYSIOLOGIC ASPECTS OF TRANSFUSION

DR. DU BOIS: Dr. Stillman will discuss the physiologic aspects and technic.

DR. RALPH G. STILLMAN: The purpose of transfusion is to introduce into the patient's circulation not necessarily fresh but sterile normal blood, usually of a high hemoglobin content, free from disease, especially

syphilis and malaria, and of the proper blood group compatible with the blood of the patient.

The practice of transfusion has been extended somewhat by the use of plasma instead of whole blood, and at times also by the use of donors that have been immunized against certain infections, but in general we want to give a product that is as near normal blood as possible and not have the administration followed by reaction. The procedure is frequently complicated by the fact that the blood may be needed in a great hurry.

The tests that are done as a routine to determine whether blood is suitable are those which tell us the blood groups of the donor and of the recipient and the compatibility of the two bloods, one of the serologic tests for syphilis and hemoglobin estimation. The board of health now requires a white cell count in donors of blood for the blood bank, and a physical examination of the donor is an important feature. In my opinion the examination of a stained blood film would be of greater value than the white cell count.

The sources of supply are professional donors, volunteer donors, placental blood and cadaver blood. Professional donors may be listed independently by hospitals which have the necessary facilities to maintain such lists or may be obtained from donor bureaus, where some of the necessary examinations are made and recorded and where the hemoglobin estimation and certain tests for the presence of syphilis are done at regular intervals. Volunteer donors are usually friends or relatives of the patient or sometimes merely altruistic persons who wish to give blood to sick people. The great value of the volunteer donor, of course, is the lack of expense for the patient or the institution. The disadvantage introduced by the use of volunteer donors is that not infrequently five, ten or fifteen donors must be examined before one that is compatible is found. When there is urgent need for the transfusion this often occupies valuable time, and it is always expensive.

In Russia cadaver blood is relied on for at least a part of the supply. Its use is said to depend on the miraculous reliquefaction of this blood after coagulation. So far as I know it has not been used in this country.

Placental blood is a generally available supply of rather small amounts of blood. For transfusions of the usual size for adults, several of these lots are combined. This source has not been utilized at the New York Hospital.

The transfusion may utilize either fresh blood or stored blood. The fresh blood has been most commonly used, whereas stored blood, while it was introduced during the last war in the British army and used to a certain extent, has recently increased in popularity with the introduction of the so-called blood banks.

Fresh blood transfusions may be done either by direct or by indirect methods, while the stored blood transfusions are necessarily all of the indirect type, in which the blood is treated with some substance to prevent its coagulation and there is a longer or shorter interval between withdrawal of the blood and its administration.

In the management of blood banks certain regulations have been generally adopted, some of which are more or less arbitrarily imposed. The blood taken from donors is treated with an anticoagulant or so-called preservative, which may differ in different places. Sodium citrate is the salt that is most frequently used. Many years ago Rous showed that the preservative effect of sodium citrate was greatly increased by the

addition of some sugar, and during the war the British used sodium citrate and dextrose. A rather elaborate mixture is used in Russia and has been adopted to some extent in this country with placental blood, to which are added not only sodium chloride and sodium citrate but traces of magnesium sulfate and potassium chloride and sometimes dextrose. The effect of the addition of dextrose to these solutions is generally recognized as aiding in the longer preservation of the red cells. The usual attitude has been that it is proper and possible to administer this blood to patients so long as the red cells remain reasonably intact, or perhaps I should say a reasonable proportion of them remain intact.

The feeling is rather general that the administration of hemolyzed cells is undesirable. There is very little experimental basis for this opinion, yet it persists in connection with the use of stored blood. The department of health regulations require that the blood shall be stored at a temperature between 1 and 5 C., that it must be preserved for not more than eighteen days and that it must be discarded on evidence of hemolysis, without stating how much hemolysis should require its rejection. As a matter of fact hemolysis first appears within twenty-four hours from the time the blood is taken. Under the most favorable conditions this hemolysis progresses exceedingly slowly, and for periods of three and even six weeks there may be only slight discoloration of the supernatant plasma; nevertheless hemolysis does begin immediately and progresses during the period of storage of blood.

A definite change which takes place in blood during storage is a loss of potassium from the cells to the plasma. It has been objected that the administration of potassium in this abnormal location may have an unfavorable effect on the patient. There seems to be very little actual basis for that fear, for bloods two months old have been given to patients without unfavorable effects.

The change which takes place in the prothrombin is not entirely agreed on. Some figures which have been published seem to show that the prothrombin diminishes rapidly and that but little is present in stored blood after the end of the first week; on the other hand, some observations have been made which seem to negate these data. Complement deteriorates rapidly and almost entirely disappears in most cases after one week's storage.

Aside from these changes, little is known about what goes on in stored blood. Blood has been administered without any apparent undesirable effect after periods up to two months. A demonstration of this point was made some two years ago when blood was taken from a donor in Buenos Aires and shipped to New York and then to Paris by steamer and there given to a patient in Paris, with what was claimed to be a desirable effect. However, it is generally felt, I think, that whole blood should be stored for not more than three or four weeks and that the absence of recognized ill effect does not mean that none has occurred. It is doubtful whether the presence of hemolysis has any really undesirable effect. In some places plasma is separated from the cells and given to patients, and it is said that the results are beneficial and free from obvious ill effects regardless of the degree of hemolysis shown by plasma.

We especially desire to avoid reactions. These reactions are of three general types: There are allergic

reactions, which are practically unavoidable and are of no moment. The patient may be uncomfortable because of the presence of urticaria, but that is usually controlled with a little epinephrine. Jaundice without a chill is apparently evidence of destruction of some of the more fragile of the red cells and is probably of very little importance, not deserving to be called a reaction. Jaundice with a chill may indicate an exceedingly dangerous and severe type of hemolytic reaction, such as one gets with a transfusion of incompatible blood, and may end fatally. The usual type of reaction which occurs with chill and a rise in temperature may be due to a number of causes, which are usually not recognized.

I can say that the direct method of transfusion is, in our experience at least, followed by a much smaller percentage of reactions than the indirect method. The direct method, however, is often awkward and when many persons are involved is not practicable.

Causes of reactions that can be recognized, besides those due to incompatibilities, are bacterial contamination, which should never happen with a properly operated bank, the use of water that is not freshly distilled in making up solutions, and the use of apparatus, especially rubber tubing, that has not been properly cleaned. As I have said, it is reasonably certain that the presence of hemolysis does not contribute to these reactions, although it is generally avoided.

DR. DU BOIS: The subject is now open for discussion or questions. Dr. Smith, will you tell us something about the work you are doing in the children's clinic?

TRANSFUSIONS DURING INFANCY AND CHILDHOOD

DR. CARL H. SMITH: I suppose there is no age period in which transfusions of blood have been used with greater frequency in recent years than during infancy and childhood. They have become a useful and in some cases an indispensable addition to treatment in pediatric practice. With the more widespread use of the intravenous rather than the intramuscular injection of blood in very young infants, however, certain precautions must be taken relative to blood matching. It is essential that preliminary blood grouping and compatibility tests be carried out in every case, no matter how young the infant, and even when the mother is the donor. It is hazardous to rely on the low titer of iso-agglutinins in the infant's blood as compared with the adult donor for the safety of a transfusion. In the newborn particularly it is important to repeat these tests before subsequent transfusions because the blood group of a baby may not be fully established at birth. In studying the development of blood groups it was noted that the infant's iso-agglutinins which were detected in the cord blood and in the peripheral blood for a variable period after birth were in large part derived from the mother through placental transfer. Reexamination within ten days revealed either a diminution in their titer or their complete disappearance. The blood group was later finally established with the elaboration by the infant of its own iso-agglutinins and receptors. The importance of those observations was illustrated by two infants whose cord blood revealed the presence of a and b iso-agglutinins and the complete absence of agglutinogens, so that the blood group could be classified as O. Within ten days the A and B agglutinogens made their respective appearance, and with the acquisition of the corresponding b and a iso-agglutinins the blood group in each case could be finally classified as A and as B. In other

words, the blood of these infants at birth fulfilled the requirements of group O by tests for receptors and for iso-agglutinins, to be replaced subsequently by their own blood groups A and B. The tardy development of iso-agglutinins and the observations that blood group elaboration appears to be accelerated after transfusions emphasize the importance of repeating blood group determinations when transfusions are to be repeated in the neonatal period.

Of the various methods that have been employed for the administration of blood, the most effective is the intravenous route. With the development of technical skill so that superficial veins, especially those of the scalp, became available, transfusions with citrated blood have been carried out for a large number of conditions in very young infants.

The conditions for which infants are given transfusions are often the same as those which occur in older patients, but there are certain states peculiar to this age period which have been greatly benefited by this form of therapy. Infants who suffer from severe malnutrition, whose weight is maintained with difficulty and whose blood volume and serum proteins are reduced show pronounced improvement with transfusions. Transfusions constitute a valuable aid in combination with parenteral fluid in the treatment of gastrointestinal intoxication. The injection of blood assists in overcoming circulatory collapse and shock and in correcting the water and electrolyte disturbances that follow vomiting, diarrhea and the attendant dehydration. Transfusion benefits the premature infant whose weight is stationary or who gains slowly and who is anemic. It has been advocated as a routine measure during the first forty-eight hours of life when the birth weight is below 1,500 Gm. Transfusions are probably of value in the treatment of cerebral hemorrhage by aiding clot formation, but here small, frequently repeated transfusions have been suggested instead of single large transfusions in order to avoid loosening of the clot at the site of the injured blood vessel. They are employed in "hemorrhagic disease of the newborn" with preference for the intravenous over the intramuscular injection. From an analysis of several series of cases, Clifford has pointed out that the value of blood transfusion in hemorrhagic disease may be attributed to combating the anemia due to the loss of blood rather than to the correction of the fundamental disorder.

In regard to the use of transfusion preoperatively, it may be said that there are circumstances peculiar to young persons where this is a justifiable procedure. I refer to infants, for instance, with hypertrophic pyloric stenosis who have been untreated or for whom medical treatment has been unsuccessful, or infants with prolonged ear infection in whom mastoiditis has developed. Such illnesses are usually associated with long drawn out periods of limited food and fluid intake. Transfusions relieve the anemia, the toxemia and the metabolic disturbances incident to malnutrition and dehydration already referred to. The probable role of transfusions in providing immune bodies may be particularly significant in young persons. Not alone may the infant be poorly supplied with immune bodies to pathogenic organisms only recently encountered, but its tissues may not yet possess sufficient maturity to elaborate them. It is conceivable that repeated transfusions may stimulate tissues to produce them in a manner similar to the accelerated development of blood groups by this procedure.

Dr. Forkner has referred to the use of transfusions in erythroblastic, or Cooley's, anemia. We have studied a number of infants and children with this blood dyscrasia, and certain features have become obvious with regard to the need for transfusions. Recent case reports have revealed that the disease is not uniformly severe and that mild and chronic cases are not uncommon, and that has been our experience also. In a case of moderate severity there are times when the blood cannot be maintained at levels compatible with well-being for any length of time without transfusions. The need for blood replacement, which in some cases necessitates weekly or biweekly transfusions, is frequently lessened by splenectomy. After this procedure and at times spontaneously the need for transfusions becomes much less frequent, and a state of chronic anemia develops in which ordinary activities are carried on without difficulty. Experience has shown that when this state is reached it is almost impossible to maintain normal blood levels for any considerable period even with repeated transfusions. When infection supervenes, however, a sudden drop in the hemoglobin and red cell count occurs and transfusions are again required.

DISCUSSION OF QUESTIONS

DR. PAUL REZNIKOFF: I should like to comment on some of the statements made by Dr. Forkner. One important point is that each case must be judged on its own merits. Another point is that it is quite possible to be misled into thinking that a transfusion has accomplished something. For example, when a patient with thrombopenic purpura is so treated, you might think that this measure caused the increase in the platelets; but they will often increase spontaneously if these patients are not given transfusions, especially when they have rather large hematomas in their tissues. Therefore it is difficult to prove that the transfusion was responsible for the increased number of platelets. The same thing is true of the statement that after a transfusion the bleeding or clotting functions have improved. It is very difficult to prove that by satisfactory evidence. I certainly think that this applies to the administration of transfusions in chronic osteomyelitis. A great many surgeons believe that transfusions improve the patient's resistance. But that is a vague term, and I doubt whether there is any good evidence to support it. I don't know how long these supposedly immune substances given by the donor last and how good they are.

There is another feature about transfusion which a physician must consider over and above the specific effect of the blood, and that is the effect of the transfusion on the emotions. There are some patients who consider a transfusion a very serious procedure. They know it is associated with serious diseases, and giving a transfusion without preparing such a patient properly will shock him. He feels he has a hopeless condition. On the other hand, you see the reverse type of case in which the family, the family physician or even the patient feels he has something wrong with his blood and that he should have a transfusion. If you do not give him this treatment he brings a lot of pressure to bear on you and may think he is not being treated properly. Those are factors which you have to evaluate in the individual case.

There is this to be said about giving a transfusion in a condition which is apparently hopeless, as in acute leukemia, aside from the waste of money: If you con-

sider such a condition hopeless—and most if not practically all of them are—is it fair to prolong a patient's agony? You would not give a transfusion as a rule to a patient with an inoperable carcinoma. Regardless of whether you think leukemia is of that nature or not, the end result is about the same. It seems to me that in such cases the general rule should be that the patient's symptoms should be treated; that is, if the patient is anoxemic the only thing that will help him is blood, and if he is not anoxemic I should think that in most cases transfusions are not indicated.

DR. DU BOIS: I am glad Dr. Reznikoff brought up that point. It is a very difficult matter, and the decision of whether or not to transfuse has been determined to a certain extent by the history of the procedure. In the early days the transfusionists had to sell the idea to the medical public. Now perhaps it has been oversold, so that physicians and the public expect too much of transfusions, and once they are started for a patient it is difficult to stop them. You may prolong life for a few days, but very often you prolong misery also. You waste a great deal of money for the patient and for the institution. So I suggest that you be very careful in starting a series of transfusions for a patient with a hopeless outlook. The same, perhaps, applies to a certain extent to oxygen tents. Are there other questions?

DR. HARRY GOLD: Could we have a restatement of the mode of action of transfusion in bringing about the beneficial effects when they occur? Is it merely a matter of supplying certain materials such as cells, hemoglobin and antibodies or is there also stimulation of certain structures or functions?

DR. FORKNER: I think both factors are concerned, but the latter to a much less extent. In other words, I think that transfusion in blood disorders usually is given to alleviate the symptoms of anemia, such as anoxemia. A greater oxygen and carbon dioxide carrying power is thus supplied to the blood, which lessens the work of the heart. After this the size of the heart may be reduced when it is dilated and there will be a less rapid respiration. I think the other factor of supplying stimulation to the blood-forming organs is a debatable one. At times patients do appear to be stimulated after a transfusion. Whether it is due directly to the transfused blood or to some secondary reaction we do not know.

DR. DU BOIS: I noticed that Dr. Smith used the word "probably" in regard to some of the beneficial effects of transfusion in infants. Is that a pretty big "probably"?

DR. SMITH: The answer to that question has to be subdivided. The beneficial effects of transfusion vary with the age of the child and with the condition for which this form of therapy is offered. The problem of judging the efficacy of transfusion at all age groups is one of measuring benefits objectively. In addition to quantitative estimation of the various blood elements following transfusion, the effect on mortality figures offers a most satisfactory gauge as to its value. This is illustrated in the syndrome of erythroblastosis foetalis, from which the mortality in untreated cases has been estimated as high as 80 per cent and which has been reduced to about 10 per cent with the use of transfusions. Yet it is difficult to determine just how transfusion has effected this remarkable improvement. The pathogenesis of this condition is obscure and a great

many theories have been offered as to its causation. It is regarded by one group as being due to a metabolic disturbance of hemopoiesis and by another as being essentially a hemolytic anemia. Transfusions elevate the hemoglobin and red blood cells and probably reinforce the supply of antihemolytic principles which usually are provided by the mother and which retard the physiologic hemolytic processes that take place in the first six weeks of life. While reference to antihemolytic factors is usually vague, there is concrete evidence of their existence in the detection by Josephs of a substance found in plasma which reduced the rate of blood destruction in sickle cell anemia and in congenital hemolytic jaundice. The effects of transfusion in erythroblastosis foetalis include the correction of the anemia, probably both by supplying the essential factors required for normal hemopoiesis and by stimulating their production. As with all anemias, transfusion also relieves the anoxemia by increasing the carriers of oxygen to the tissues. It is probably true, however, that this condition is self limited and that transfusions are supportive, in the sense that they tide the infant over the acute stages of this blood dyscrasia until normal blood formation is established. Transfusions must be carefully regulated, however, so as not to aggravate hemolysis.

When one comes to the older group, it is often difficult to justify transfusions and the qualification of "probably" looms big. It has already been stated that to the child, regardless of age, who has been ill for a long time with infection, transfusion is given as a supportive measure until immunity develops or until a particular operative procedure has been successfully accomplished. In the absence of anemia or of the effects of dehydration, it is difficult to determine when a child is in need of a transfusion.

Transfusions have enjoyed a definite vogue in the treatment of pneumonia. When it has occurred in young debilitated infants or when it has complicated contagious disease, transfusions are justified for the many reasons already mentioned. Until the recent introduction of chemotherapy, transfusions had been employed, however, as a routine procedure in the treatment of pneumococcic pneumonia. In this case the actual contribution of transfusions to recovery has always been problematic because children do so well without any specific therapeutic program. They were originally suggested as a form of therapy for pneumonia complicated by anemia. They have since been employed, however, in the absence of anemia and have been justified as a means of supplying antibodies, of increasing the amount of oxygen to the tissues by replacing the erythrocytes sequestered in the diseased lung, and of precipitating a critical drop in temperature. While spectacular improvement in the clinical course of this disease has been observed after transfusions, it is doubtful whether statistical analysis of large series of cases without this form of therapy would not reveal an equal number of similar changes.

DR. SALMON HALPERN: I should like to mention a few practical points that have arisen in the pediatric service. Since we have utilized the blood bank, using blood which is sometimes eight, ten or twelve days old, we have seen an increasingly large number of reactions. We have been trying to trace the cause of these reactions. Until recently we kept our blood bank at 18 C. The blood is now kept at 5 C. and just before

use is put in a pan of warm water at about 38 C. Heat is applied only to the actual quantity of blood to be injected. We think, and it has apparently been the experience in Bellevue Hospital where a bank has been long in existence, that repeated warming is probably one of the causes of reactions, especially when the blood is older. I wonder if Dr. Stillman would tell us whether he feels, as we do, that heat could cause the reaction.

DR. STILLMAN: I have no doubt that variations in the temperature might facilitate destruction of the red cells. I think it is a perfectly good procedure to remove only a portion of the cold blood and thus to avoid warming and then cooling blood to be used later. However, we have no idea of the cause of most of the reactions.

DR. DU BOIS: The blood bank is under fire quite often. I think reactions have occurred more frequently throughout the hospital since the introduction of the blood bank.

DR. STILLMAN: There was a period when the reactions were much more frequent, and now they are again becoming much less frequent without any reason that we can determine.

DR. McKEEN CATTELL: In view of Dr. Stillman's impression that a small amount of hemolysis does not of itself constitute a contraindication to the use of stored blood, it is of interest to note that Amberson has shown experimentally that dogs survived for a number of days after bleeding and replacement with laked blood. He was thus able to demonstrate the lack of toxicity of free hemoglobin and the fact that, in this state, it continued to function in the transport of oxygen and carbon dioxide.

DR. H. B. RICHARDSON: There is one point that has not been sufficiently stressed. I recall rather definitely a story given as an explanation for reactions; somebody noticed that when an old worn piece of rubber tubing used for injections was replaced with a new one there was a series of reactions.

DR. STILLMAN: The preparation of the apparatus, of course, includes rubber tubing, which is very important.

DR. JOHN F. DEITRICK: I should like to ask if the condition of the donor makes any difference in reactions. It has been said that if a donor is alcoholic or has recently had a large meal the incidence of reactions goes up.

DR. STILLMAN: So far as the question of donor's food is concerned, I do not think it is of any importance in most cases. I think, however, that in the allergic patient one may encounter reactions. We have never regarded hives and asthma and that sort of thing as significant; they are of minor importance as a rule and can be avoided by having the donors fasting when the blood is taken.

DR. DEITRICK: Another point about the temperature of the transfusion: I happened to be at the Lederle Laboratories when they were giving a large transfusion from one animal to another and using 2, 3 or 4 liters of blood. I asked them why they did not warm the blood. Their reply was that they then got more reactions. They said that in the first instance one of their men made a mistake and gave the blood cold from the ice box, and, while they used to get severe reactions from warm blood, since they have been transfusing it cold they have had practically none. They had no explanation for it. It aroused my curiosity.

DR. WILLIAM DEWITT ANDRUS: I think Dr. Stillman will agree with me when I say that you can do many things in transfusions with the animal that you not only would hesitate to do but could not do with the human being.

DR. STILLMAN: I know there are many instances of transfusions and infusions being given at various temperatures below the body temperature. Here, again, I am relying on experience. The only chill that I know to have occurred from the infusion of physiologic solution of sodium chloride in the old New York Hospital occurred in a patient who was a member of the staff at that time; in this instance the saline solution was not warmed at all but given at room temperature. It may have been a coincidence, but chills are rare with that fluid.

DR. DU BOIS: If a man is anywhere near the edge of a chill, it can be precipitated by a small amount of cold water taken into the stomach, so it certainly could be precipitated by the transfusion of cold water into the veins.

I should also like to point out that man is accustomed to receiving large quantities of cold blood from his cold hands and feet. We find in experiments with the calorimeter in a cold room that the surface of the toes, for example, is often colder than the air. The hands are often as cold as the air, so man is accustomed to getting cold blood, and the veins returning from the hands and feet are cold streaks along the arms and legs.

DR. FORKNER: I would like to make one more point, and that is that the recent studies done, particularly by Kolmer, suggest that blood bank blood is not satisfactory for use in certain types of blood diseases, particularly in the thrombopenic group, because according to these studies the platelets are destroyed within a very short time, from twenty-four to forty-eight hours, and within a period of five days they are practically nonexistent. Another thing is that white blood cells begin to be destroyed promptly and within the course of seven or eight days are much reduced in number.

DR. REZNIKOFF: Why does Dr. Stillman do a white cell count as a test for the suitability of a donor?

DR. STILLMAN: Because the board of health requires it. I think a blood smear would be of more value.

STUDENT: Could some one tell us about the relative value of blood bank blood and fresh blood in treating infections? Do the antibodies in the complement deteriorate rapidly? I have been given to understand that for infections about 100 cc. of fresh blood is as good as 500 cc. of stored blood.

DR. REZNIKOFF: We ought first to decide whether any amount of blood is good for infections.

DR. FORKNER: I think it is very much open to question whether blood is good for infections.

DR. STILLMAN: Antibodies in transfusions are of doubtful value, and if antibodies are present they probably would be maintained in stored blood. The complement of course will disappear after a few days.

DR. GOLD: Dr. Forkner stated the criteria for the use of blood transfusions in anemia to be a low red cell count and low hemoglobin, and I believe he also said that after acute hemorrhage even in the presence of a normal red count and normal hemoglobin one may have to give a transfusion, and it might be lifesaving. May we assume that blood transfusion in other blood

diseases is also indicated only when the red cell count and hemoglobin are at low levels?

DR. FORKNER: The reason for the statement that the red cell count may be normal is that the blood may not yet have had time to dilute itself to reestablish the normal blood volume; i. e., immediately after an acute hemorrhage the blood has not absorbed fluid from the tissues, so that even though the total hemoglobin and the total red count of the body are decreased it is not at once reflected in the blood composition. The spontaneous restoration of blood volume is much delayed in the presence of shock.

In hemophilia it is not so much a matter of the red cell count and of the hemoglobin as it is the supplying of some other factor, a factor which has recently been shown by Stetson, Taylor, Eagle and others to be present in normal blood plasma or blood serum, which is not present in the blood of a hemophiliac, and which reduces the coagulation time. Also in cases of purpura haemorrhagica when the patients are bleeding, even though they have not a critical level of red cells and white cells, one supplies platelets to stop the bleeding.

DR. ADE T. MILHORAT: On the face of it, the use of an anticoagulant like a citrate would seem to be inadvisable in giving a transfusion to patients with hemorrhage. I was wondering if Dr. Cattell would say a few words about that.

DR. CATTELL: I do not have special information on the problem, but I should think in the first place that the amount of citrate is probably not very much in excess of the amount required to prevent coagulation in the donor blood so that its effect in deionizing the calcium in the recipient's blood would not be large; secondly the injection of citrates into animals has the opposite effect, that is, the coagulation time is shortened, presumably owing to an action on the endothelial walls or platelets.

SUMMARY

DR. DU BOIS: Every one seems to be agreed that today we are riding the crest of a wave of enthusiasm for transfusion; that transfusions are used too freely and often in conditions in which they appear to do little or no good.

The purpose of additional blood in most cases in which transfusion is indicated is to alleviate anoxemia due to anemia. The oxygen and carbon dioxide combining power of the blood is augmented by this process; the burden placed on the heart by severe anemia is reduced. There are also other uses for transfusion. In the hemorrhagic states new blood may introduce those elements which aid in the coagulation of blood. There is considerable doubt whether transfused blood is of specific value in combating infections, but on the other hand a transfusion may tide an anemic patient over a crisis, after which he may be better able to combat the infection.

Transfusion is indicated when the red blood cell count falls to about 2 million cells per cubic millimeter and the hemoglobin to about 5 to 6 Gm. per hundred cubic centimeters. In sudden severe hemorrhage, however, transfusion is indicated immediately, although the red cell count and the hemoglobin may not have fallen appreciably because hemal dilution has not yet occurred.

Transfusion may be contraindicated in bleeding peptic ulcers and in the presence of pulmonary edema and of cardiac decompensation. If absolutely essential in these conditions, the blood should be administered slowly and in small amounts.

The indications for transfusions in infants are much the same as in adults. They are also useful in the treatment of premature infants, severe malnutrition and gastrointestinal intoxication. In infants it is important to type the blood and perform compatibility tests before each transfusion because frequently the blood group is not established at birth.

Hemolysis does not appear to decrease the value of stored blood seriously in most instances, but the thrombocytes deteriorate rapidly and fresh blood may be preferable to preserved blood in the treatment of some of the blood dyscrasias, especially the hemorrhagic states.

Reactions to transfusions may occur even when scrupulous attention is paid to typing, compatibility and the apparatus. Urticaria, jaundice or chills are not particularly serious, but jaundice with a chill may indicate a severe type of hemolytic reaction. These appear to occur less frequently with the direct method of transfusion.

THYROID MEDICATION DURING CHILDHOOD

LAWSON WILKINS, M.D.

BALTIMORE

Thyroid medication during childhood will be discussed under two headings: (1) substitution therapy in definite thyroid insufficiency and (2) the administration of thyroid in borderline conditions of questionable thyroid origin, in supposedly mixed endocrine disturbances and in conditions not hypothyroid in which the physiologic effects of the drug are sought. It is necessary first to mention briefly the diagnostic problems of hypothyroidism in childhood.

THE DIAGNOSIS OF HYPOTHYROIDISM IN CHILDHOOD

Cretinism.—The untreated cretin of more than 2 or 3 years of age usually presents a picture which is well known and easily recognized.¹ The patient is dull, listless and apathetic. The body is short and stocky. The cretinoid facies is characterized by coarse, heavy features; small, widely spaced piglike eyes with puffy lids; a broad, short nose with undeveloped bridge; a broad mouth with thick lips, and a broad protruding tongue. The skin is dry, thick, wrinkled and cool and shows circulatory mottling. The cheeks are pale and may have a carotenemic tinge. The lips are pale or slightly dusky. The hair is sparse, coarse and dry.

In the first year or two of life, the time when adequate treatment offers the most favorable prognosis, the cretin frequently does not have this characteristic and easily recognizable appearance. On superficial inspection he might be mistaken for a fairly normal infant considerably younger than his actual age. For example, a cretin of 18 months may look and act like an infant of 5 or 6 months. This is due to the fact that the thyroid deficiency causes a retardation of all the developmental processes—growth, osseous development, dentition and mental development. The x-ray study of the centers of ossification and a comparison with Shelton's² tables to determine the bone age is an essential diagnostic

1. Kennedy, R. L. J.: *The Thyroid Gland*, in Brennemann, Joseph: *Practice of Pediatrics*, Hagerstown, Md., W. F. Prior Company, Inc., 1937, vol. 1, c. 38.

2. Shelton, E. K.: *Roentgenographic Studies in Normal Osseous Development*, J. A. M. A. 96:759 (March 7) 1931.

procedure. In the untreated case, unless there is a definite retardation in the osseous development, growth, dentition and mental development, cretinism can be excluded. On the other hand, the diagnosis can be established with certainty only by finding, on careful examination, some of the changes of the skin and hair and the apathy which are common to hypothyroidism. The finding of a serum cholesterol above 300 mg. per hundred cubic centimeters is strongly suggestive of hypothyroidism, but in untreated cretinism the cholesterol may be within normal limits. The diagnosis should not be considered as established unless adequate dosage with thyroid causes striking clinical changes, a marked acceleration of growth and osseous development and a drop in the serum cholesterol.

Mistakes in diagnosis are made frequently. The condition is unsuspected sometimes until the child is 3 or 4 years old. Children with mongolian idiocy or other cerebral defects often are labeled cretins. Hypertelorism,³ a developmental defect of the sphenoid bone causing a wide spacing of the eyes, may produce a facies somewhat suggestive of the cretinoid. When a child has been treated previously with thyroid the diagnosis is made still more difficult, because all the characteristic signs may have disappeared. If the original diagnosis is open to serious question, thyroid should be discontinued and the patient should be observed carefully over a period of from four to ten weeks. If hypothyroidism exists, the patient will become more sluggish, the weight will increase rapidly, the color of the skin and lips will fade and finally the skin will become cool, dry and rough. Most characteristic of all after the withdrawal of thyroid, the serum cholesterol will rise to high levels—usually to between 300 and 400 mg. per hundred cubic centimeters and at times over 600 mg.

Juvenile Hypothyroidism.—Terms used synonymously by various writers are acquired hypothyroidism, juvenile myxedema and hypothyroid dwarfism. In this condition one cannot be certain whether a previously normal thyroid has become deficient or whether the gland, partially deficient from birth, has been able to fulfil the needs of the young infant but not the increased demands of the older child. In most instances the patient seems to have grown and developed during the first few years of life. Later there is a slowing or stopping of growth and development, so that the child lags further and further behind the normal for his age. The characteristic cretinoid facies does not develop, nor do the myxedematous deposits of the adult usually occur. The typical case of juvenile hypothyroidism may be described as follows: The child looks much younger than his actual years. He is stunted in height, with skeletal proportions corresponding to his height rather than to his age. The body build is stocky or chunky. The patient is overweight but not markedly obese. The features are somewhat broad and coarse and the expression is a little dull. There is always marked delay in the osseous development. The second dentition is delayed and the teeth are often poorly formed and carious. The mental development is usually somewhat retarded. The cheeks and lips are generally pale. The skin is cool, somewhat dry and roughened, and the hair is dry. However, changes of the skin and hair are usually much less marked than in cretinism.

There may be considerable deviation from the characteristic clinical picture, so that certain special examinations are of considerable diagnostic value. The determination of the basal metabolic rate is often unsatisfactory and unreliable. The x-ray study of the centers of ossification is of great importance. If hypothyroidism has existed for several years, the bone age is always definitely retarded. Unless this retardation is found, the diagnosis can be excluded. However, contrary to the opinion expressed by some writers, delayed osseous development of itself is not always pathognomonic of hypothyroidism but may be found in other types of dwarfism. Of still greater diagnostic importance is the additional finding in some cases of a porous, stippled or fragmented appearance of the osseous centers, described by a number of authors, and recently given the name of cretinoid epiphysial dysgenesis by Reilly and Smyth.⁴ This resembles bilateral Perthes' disease or Köhler's disease and is not usually encountered in types of dwarfism which are not of hypothyroid origin. It disappears rapidly under treatment. In juvenile hypothyroidism the serum cholesterol is usually from 300 to 500 mg. per hundred cubic centimeters. It is subject to wide spontaneous fluctuation so that at times it is within the limits of normal. The urinary excretion of creatine is greatly diminished or absent. As in all hypothyroid conditions, the most important criterion for diagnosis is a specific response to comparatively small doses of thyroid: a sharp drop

Therapeutic Equivalents of Brands of Thyroid

		Fresh Gland, Grains	Thy- roxine, Mg.
Thyroid U. S. P.....	1 grain	= 5.0	= 0.2
Parke, Davis & Co.....	1 grain	= 7.5	= 0.3
Burroughs, Wellcome & Co.....	1 grain	= 1.5	= 0.06

in the serum cholesterol, a rapid increase in the creatine excretion, an acceleration of the osseous development and rate of growth and a disappearance of the physical signs of hypothyroidism.

THE USE OF THYROID IN DEFINITE HYPO- THYROID CONDITIONS

Thyroid Preparations.—Desiccated thyroid by mouth is the therapeutic agent of preference. Pure thyroxine has no advantage over dried thyroid and, by mouth, is probably inferior. Other fancy and more expensive thyroid pharmaceuticals have nothing to recommend them. If the child is unable to swallow a thyroid tablet, it may be crushed and given in the food. A single daily dose is as efficacious as divided doses.

The U. S. Pharmacopeia XI requires that desiccated thyroid contain between 0.17 and 0.23 per cent of iodine in thyroid combinations. One part corresponds to approximately five parts of fresh gland. Unfortunately, not all commercial brands conform to this requirement, and this leads to confusion in dosage. According to Lerman and Salter⁵ and to Means,⁶ the therapeutic equivalents⁷ of various brands of thyroid are given in the accompanying table.

4. Reilly, W. A., and Smyth, F. S.: Cretinoid Epiphysial Dysgenesis, *J. Pediat.* **11**: 786 (Dec.) 1937.

5. Lerman, Jacob, and Salter, W. T.: The Calorigenic Action of Thyroid and Some of Its Active Constituents, *Endocrinology* **18**: 317 (May-June) 1934.

6. Means, J. H.: Therapeutics of the Thyroid, *J. A. M. A.* **105**: 24 (July 6) 1935.

7. The therapeutic equivalents of thyroid and thyroxine, as indicated in the table, are not to be confused with the actual thyroxine content of thyroid, since the activity of thyroid is recognized to be due to more than thyroxine content alone.

3. Washington, J. A.: Hypertelorism, in Brennemann's Practice of Pediatrics, vol. 4, c. 31.

The physician would do well to stick to one commercial brand—preferably one fulfilling the U. S. P. requirements—and he should specify this brand on the prescription. The failure to realize the difference between the American and the British standardization has led frequently to serious underdosage.

Principles of Thyroid Treatment in Children.—Although in general the principles of substitution therapy are the same in childhood as in later life, there are some important differences to be borne in mind:

1. Means⁶ states that "in adult myxedema, the indication is to give a sufficient daily ration of thyroid to keep the patient free from symptoms. It is best to use the minimum dose that will accomplish this purpose. Nothing is gained by raising the basal metabolic rate to standard if the patient is free from symptoms (as is usually the case) at a decidedly lower level." This is not true in childhood. The rate of growth and development is largely governed by thyroid activity. If less

Chart 1.—Height age, bone age and mental age, compared with the normal, of cretin adequately treated.

thyroid is given than is required to maintain a normal level of metabolism, the developmental rate will be slower than normal. As the child grows older, he will fall further and further below the normal standards for his age. If just sufficient thyroid is supplied to meet the normal requirement, the previously stunted hypothyroid child will probably grow and develop at the normal rate but will not attain the normal levels for his age. In order to accelerate the developmental rate sufficiently to allow the retarded hypothyroid patient to make up for his lost years and to approach his normal age level, it is probably necessary to produce a slight degree of hyperthyroidism. Therefore in childhood it seems important to give at least sufficient thyroid to maintain a normal metabolic rate and, accordingly, a normal rate of development. I believe that perhaps even better results can be obtained by producing a very slight degree of hyperthyroidism. With reasonable care to avoid toxic symptoms, this can be done without danger to the patient. Demineralization of the bones has not been observed. Whether such acceleration of the development causes the child to reach the optimal physical and mental attainments

remains to be proved. At the present time the results seem to be more favorable than with the small doses previously advocated.

2. The dose of thyroid tolerated without toxic effects is not proportional to the size, weight or age of the child. The young cretin usually can tolerate from 1 to 3 grains (64 to 192 mg.) of thyroid—as much as a 12 years old child with juvenile hypothyroidism or an adult with myxedema. The small doses^{7a} that are usually recommended for cretinism are based on the requirements necessary to cause disappearance of the cretinoid facies, the changes of the skin and hair and the other obvious signs of cretinism. Such doses do not usually cause the child to grow and develop at a normal or slightly accelerated rate, and they lead to the loss of much valuable time in the early years of life.

3. It is necessary to determine the tolerance of each patient. Like the myxedematous adult, the hypothyroid child is much more sensitive to thyroid than the normal individual. At the beginning of treatment, toxic symptoms may be produced by from one half to 1 grain (32 to 64 mg.), whereas after some months of therapy the dose may be increased gradually to as much as 2 to 3 grains (128 to 192 mg.) without ill effect. As the tolerance increases it is important to raise the dose in order to maintain an adequate rate of development. It is rarely, if ever, necessary to exceed 3 grains (192 mg.) daily.

Regulation of Dosage.—Since the therapeutic objective is to bring the hypothyroid child as close as possible to the normal level of physical and mental development it is desirable to give sufficient thyroid to maintain the metabolism at the normal level or slightly above it. However, the determination of the basal metabolic rate often is unreliable in childhood and does not give the desired information concerning the physiologic effects. Therefore the dose must be determined and the results followed in two ways: 1. The tolerance must be found by trial for each patient; that is, the daily dose which produces slight but unpleasant toxic effects. The therapeutic dose should be maintained slightly below this level. 2. After the patient has been put on the maximum tolerated dose of thyroid, the rates of growth and development should be constantly followed as a guide to the efficacy of therapy. These methods of regulation will now be discussed in detail.

1. Determination of Tolerance: While the tolerance is being determined, the patient should be under close observation, preferably in a hospital. Even the young infant may be started safely with one half grain (32 mg.) of thyroid daily, and the dose may be increased by increments of one half grain. Since Means and Lerman⁸ have shown that, when a constant daily dose of thyroid is given, maximum effects are not exerted for approximately three weeks, it is safest to increase the dose not oftener than every three or four weeks. With the beginning of effective treatment, considerable

7a. The daily doses of thyroid recommended by most authors for the treatment of cretins are:

Age	Daily Dose
2-4 months	1/40 grain
4-8 months	2/40 grain
8-12 months	3/40-7/40 grain
12-24 months	3/10-1/2 grain
2-4 years	1/2-1 grain
4-12 years	1-3 grains

8. Means, J. H., and Lerman, Jacob: Symptomatology of Myxedema: Its Relation to Metabolic Levels, Time Intervals and Rations of Thyroid, Arch. Int. Med. 55:1 (Jan.) 1935.

loss of weight and sweating may occur. Cretins who have previously been phlegmatic and amenable may become very hyperactive, irritable, distractible and hard to manage, as are other mentally defective children. These symptoms usually may be disregarded. They probably indicate a slight degree of hyperthyroidism, which is desirable. The toxic symptoms that indicate overdosage are diarrhea or cramps, vomiting, excessive irritability or twitchings, continued loss of weight, a very rapid pulse rate and fever. If such symptoms occur, thyroid should be omitted for a few days or a week and then resumed at a level one half grain below that previously given. Cretins and patients with juvenile hypothyroidism usually can be maintained just below the level of toxic effects on daily doses of from $1\frac{1}{2}$ to 3 grains (96 to 192 mg.) of thyroid, although occasionally a patient is more sensitive than this at the beginning of treatment.

2. The Rate of Development as a Guide to the Adequacy of Treatment: Even with the very small doses of thyroid that have been used so often in the past, all obvious signs of hypothyroidism may disappear within a few weeks or months. The patient becomes more alert and energetic, the excess weight is lost, the skin becomes soft, warm and moist, the cretinoid facies disappears and a certain amount of growth may occur. One may be deceived into believing that satisfactory or optimal results are being obtained unless a careful record of the growth and development is kept. The

rate of development, especially the osseous development, probably gives the most reliable information concerning the average level of cellular metabolism over long periods of time. If after two to six months there is no acceleration of the bone development shown by x-ray examination, the dose of thyroid is probably inadequate. I⁹ have described a simple method of comparing the growth, osseous development and mental development with the normal rates. My studies have shown that with small doses of thyroid, or with interrupted treatment, the "bone

horizontal and the patient's developmental age along the vertical coordinates. Chart 1 shows the acceleration of development which adequate thyroid therapy brought about in a young cretin. The bone age rapidly approached the normal. Chart 2 shows a similar result in an older child with juvenile hypo-

Chart 3.—Height age, bone age and mental age, compared with the normal, of a cretin: results of interrupted treatment.

thyroidism. Chart 3 shows the effect of interrupted treatment in a case of cretinism. During the first year of treatment there was a subnormal rate of growth and osseous development resulting from the mother's failure to give thyroid continuously. Following this a period of regular therapy caused a marked acceleration of the osseous development. Between the ages of 4 and 5 years the omission of treatment again caused a retardation of growth and bone development. Chart 4 shows the results of inadequate dosage in a cretin. Between the ages of 6 years and 10½ years this patient received regular daily doses of one half to 1 grain (32 to 64 mg.) of thyroid. Although all clinical signs of hypothyroidism disappeared, the growth and osseous development continued to lag far below the normal. When the dose of thyroid was increased to 3 grains (192 mg.) at the age of 11½ years, a rapid acceleration of the developmental rates resulted. In this case developmental curves gave the only indication of the inadequacy of treatment.

In order to follow the rate of development, the patient should be kept under frequent observation. Roentgenograms should be taken to study the centers of ossification, first at intervals of three or four months, later every six months or year. The height should be recorded regularly and mental standardizations made from time to time. These may be plotted in comparison with the normal by the method described. Unless there is a continuous rapid development of the osseous system, one should attempt to increase the dose of thyroid to a higher level, as the patient's tolerance may have increased. If the bone age exceeds the normal or advances too far beyond the height age, the dose should be decreased, because when the bone age reaches that of 13 or 14 years epiphyseal union begins to occur and growth is brought to an end.

Chart 2.—Height age, bone age and mental age, compared with the normal, of hypothyroid dwarf adequately treated.

age" and "height age" lag further and further below the normal levels, whereas when the dose is increased to the point of tolerance they tend to approach the normal.

This is illustrated by charts 1, 2, 3 and 4, in which the chronological age is plotted along the

9. Wilkins, Lawson: The Rates of Growth, Osseous Development and Mental Development in Cretins as a Guide to Thyroid Treatment. *J. Pediat.* 12: 429 (April) 1938.

PROGNOSIS

In cases of cretinism, the prognosis for attaining approximately normal growth and physical development is good, provided treatment is adequate and not too long delayed. Unfortunately the prognosis is much poorer for normal mental attainment. Many cretins remain somewhat subnormal, and not a few remain markedly defective in mentality. This is often attributable to delay in the beginning of treatment, to inadequate dosage or to frequent interruptions in the continuity of treatment. As a rule, the earlier intensive treatment is begun, the better is the prognosis. However, it is probable that in some instances the thyroid insufficiency has caused an irreparable damage to the nervous system in the earliest months of infancy. Sometimes older cretinous imbeciles are encountered who are made only more irritable, peevish and unmanageable by intensive thyroid treatment. If a conscientious and adequate therapeutic trial has proved that one can expect no further mental development, it is probably best to be content to administer the

minimal dose required to prevent outspoken hypothyroid symptoms.

In juvenile hypothyroid dwarfism, adequate treatment usually brings about a spectacular and gratifying acceleration of growth. This continues until the osseous development reaches the stage of epiphysal union, usually simultaneously with sexual maturation. The ultimate height that the patient attains depends on the amount of stunting before treatment, the age at which thyroid treatment is begun and interrelationships with other endocrine glands, which are still little understood. The degree of mental retardation before treatment is often not marked and probably depends on the age of onset of hypothyroidism and the degree of insufficiency. The prognosis for normal mental attainment is much better than in cretinism.

Chart 4.—Height age, bone age and mental age, compared with the normal, of a cretin inadequately treated.

relationships with other endocrine glands, which are still little understood. The degree of mental retardation before treatment is often not marked and probably depends on the age of onset of hypothyroidism and the degree of insufficiency. The prognosis for normal mental attainment is much better than in cretinism.

THE USE OF THYROID IN CONDITIONS OF QUESTIONABLE OR BORDERLINE THYROID INSUFFICIENCY AND IN CONDITIONS WHICH ARE NOT OF HYPOTHYROID ORIGIN

In recent years it has become popular to ascribe various abnormalities in childhood to hypothyroidism. Frequently the mentally subnormal or the physically stunted child is glibly diagnosed as hypothyroid, provided the x-ray examination reveals some delay in osseous development, even though there are no other physical signs of biochemical changes of thyroid insufficiency. It is unwarranted to assume that the

finding of osseous retardation alone proves a thyroid deficiency, although it is probable that slowing of growth and osseous development may be the earliest evidence of hypothyroidism to become manifest. Whether slight subclinical degrees of hypothyroidism may exist without ever progressing to more outspoken forms is a most important question about which there is considerable difference of opinion. In fact, Means and Lerman⁸ go so far as to state that an adult either does or does not have hypothyroidism. "Borderline or half-way types of hypothyroidism exist either not at all or rarely. Hypometabolism is no more synonymous with hypothyroidism than fever is synonymous with measles." Unfortunately, at the present time no exact criteria have been established for the diagnosis of slight degrees of thyroid insufficiency and many such diagnoses are purely guesswork. I do not wish to condemn the empirical therapeutic trial of thyroid in children who are subnormal mentally or physically and are retarded in their osseous development. In fact, these patients should be given every benefit of the doubt. Thyroid can do no harm, if used properly, and may do some good. Such patients are probably less sensitive to thyroid than the typical hypothyroid patient, and larger doses may be required to produce any physiologic effect. It is, however, timely to utter a protest against the indiscriminate and uncritical diagnosis of borderline hypothyroidism. The clinician should endeavor to evaluate critically any apparent benefits derived from thyroid medication and should remember that it may produce nonspecific effects in the absence of thyroid insufficiency. The results should be checked later by discontinuing the drug and noting the effects of withdrawal on the physical signs and especially on the serum cholesterol. The patient should not be condemned needlessly to lifelong treatment.

The diagnosis of the various types of dwarfism is still far from established, in spite of many didactic statements in the literature. Osseous retardation of high degree is found in many different types that present no suspicions of hypothyroidism.¹¹

It is stated that preparations of pituitary growth hormone are more efficacious when given in conjunction with thyroid.¹² Their simultaneous use is justified by animal experimentation.¹³ Such double medication, however, makes more difficult the diagnostic problem of dwarfism and the evaluation of the efficacy of pituitary preparations.

Dorff¹⁴ believes that in certain types of hypogonadism there is an associated hypothyroid factor, and he combines the use of thyroid with the gonadotropic hormone of pregnancy urine (A. P. L.). Jacobsen and Cramer¹⁵ have claimed that the combined use of thyroid and of anterior pituitary extract (A. P. E.) in cases of obesity of the Fröhlich type has caused a reduction in weight and a change in body build, although

neither hormone used alone was effective. Their results have not been duplicated by others. Although the interpretation of such results is questionable, there can be no objection to the trial of thyroid.

In contrast to its use as a biologic substitution therapy in hypothyroid conditions, thyroid is sometimes employed in a variety of nonthyroid conditions, such as obesity, ichthyosis and nephrosis. In such conditions it is employed for its calorogenic, diaphoretic or diuretic action, and perhaps larger doses are needed. "The effect of thyroid in hypothyroidism is definite, precise and predictable; in nonthyroid conditions its action is often indefinite and disappointing."⁶

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.
PAUL NICHOLAS LEECH, Secretary.

DESIGNATIONS "PYRIDOXINE" AND "PYRIDOXINE HYDROCHLORIDE" FOR VITAMIN B₆ AND VITAMIN B₆ HYDROCHLORIDE

Merck & Co., Inc., brought to the attention of the Council on Pharmacy and Chemistry the proposal of Paul György of the designation "pyridoxine" (pronounced pī-rī-dōx'ēn) as an appropriate term for vitamin B₆. The company further stated that since it was about to manufacture the hydrochloride of vitamin B₆ it was desirous of approaching the Council in the matter of nomenclature.

The Committee on Nomenclature entered into correspondence with Dr. György and with representatives of the committees on nomenclature of the American Chemical Society, the American Society of Biological Chemists, and the American Institute of Nutrition, as well as others. After considerable exchange of opinions the Committee on Nomenclature recommended, and the Council adopted the recommendation, that the name "pyridoxine" be adopted as the nonproprietary term for the product tentatively known as vitamin B₆, and "pyridoxine hydrochloride" for the product tentatively known as vitamin B₆ hydrochloride. No brand has been accepted as yet by the Council.

"SULFATHIAZOLE" AND "SULFAMETHYLTHIAZOLE" THE NONPROPRIETARY NAMES FOR 2-SULFANILAMIDOTHIAZOLE AND 2-SULFANILAMIDO-4-METHYLTHIAZOLE

Two substances having current interest and also some promise of merit are 2-sulfanilamidothiazole and 2-sulfanilamido-4-methylthiazole. These preparations have been called "sulfathiazole" and "sulfamethylthiazole." At the time of the publication of the preliminary report of Dr. Perrin H. Long on these substances issued under the auspices of the Council on Pharmacy and Chemistry (THE JOURNAL, March 9, p. 870) it was stated that the Council had not yet passed on the terminology.

The Committee on Nomenclature of the Council received the information that the terms "sulfathiazole" and "sulfamethylthiazole" were acceptable to Dr. Fosbinder, who is credited as the discoverer of the products, and would be considered nonproprietary designations. Inquiry was also made of Dr. E. J. Crane, chairman of the Committee on Nomenclature of the American Chemical Society, who also informed the Council that, in his opinion, there was no objection to offer to these nonproprietary names.

Accordingly, the Council adopted the recommendation of its Committee on Nomenclature that the terms "sulfathiazole" (sulf-

a-thiazole) and "sulfamethylthiazole" (sulf-a-methyl-thiazole) be accepted as nonproprietary designations for 2-sulfanilamidothiazole and 2-sulfanilamido-4-methylthiazole, respectively. The adoption of these terms does not indicate at this time the acceptance of the substances. It is to be emphasized that the preliminary observations on sulfamethylthiazole indicate that its use may not be without considerable danger of peripheral neuritis.

No brand of either drug has yet been accepted by the Council.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

BENZEDRINE SULFATE (See New and Nonofficial Remedies, 1940, p. 233).

The following dosage form has been accepted:

Benzedrine Sulfate Ampoules, 10 mg., 1 cc.: Each cubic centimeter contains 10 mg. of benzedrine sulfate-N. N. R. in sterile water made isotonic with sodium chloride.

EPHEDRINE SULFATE-ABBOTT (See New and Nonofficial Remedies, 1940, p. 240).

The following dosage form has been accepted:

Ampoules Ephedrine Sulfate-Abbott, 0.025 Gm. ($\frac{3}{8}$ grain) 1 cc.: Each cubic centimeter contains ephedrine sulfate 0.025 Gm. ($\frac{3}{8}$ grain) in chemically pure water.

GOLD SODIUM THIOSULFATE-ABBOTT (See New and Nonofficial Remedies, 1940, p. 269).

The following dosage form has been accepted:

Ampoules Gold Sodium Thiosulfate-Abbott, 0.075 Gm.

EPHEDRINE (See New and Nonofficial Remedies, 1940, p. 235).

Ephedrine Alkaloid-Squibb.—A brand of ephedrine-U. S. P.

Manufactured by E. R. Squibb & Sons, New York. No U. S. patent or trademark.

Ephedrine Compound Inhalant-Squibb: A solution of ephedrine alkaloid containing ephedrine alkaloid 1.0 Gm., camphor 0.6 Gm., menthol 0.6 Gm., and oil of thyme 0.3 cc. dissolved in light mineral oil base to make 100 cc.

Ephedrine Inhalant Plain-Squibb: A 1% solution of ephedrine alkaloid in a lilac scented mineral oil base.

EPHEDRINE SULFATE (See New and Nonofficial Remedies, 1940, p. 240).

Ephedrine Sulfate-Squibb.—A brand of ephedrine sulfate-U. S. P.

Manufactured by E. R. Squibb & Sons, New York. No U. S. patent or trademark.

Capsules Ephedrine Sulfate-Squibb, $\frac{3}{8}$ grain.

Capsules Ephedrine Sulfate-Squibb, $\frac{3}{4}$ grain.

SULFANILAMIDE (See New and Nonofficial Remedies, 1940, p. 489).

The following dosage form has been accepted:

Compressed Tablets Sulfanilamide-Miller, 5 grains.

Prepared by the E. S. Miller Laboratories, Inc., Los Angeles. No U. S. patent or trademark.

CAFFEINE WITH SODIUM BENZOATE (See New and Nonofficial Remedies, 1940, p. 168).

The Upjohn Co., Kalamazoo, Mich.

Ampoules Sterile Solution Caffeine with Sodium Benzoate, 0.5 Gm. ($\frac{7}{16}$ grains) 2 cc.: Each 2 cc. contains caffeine with sodium benzoate-U. S. P. 0.5 Gm. ($\frac{7}{16}$ grains) in distilled water.

Hypodermic Tablets Caffeine with Sodium Benzoate, 0.065 Gm. ($\frac{1}{4}$ grain).

The Lakeside Laboratories, Inc., Milwaukee.

Ampoules Caffeine with Sodium Benzoate-Lakeside, 0.24 Gm. ($\frac{3}{4}$ grains) 2 cc.: An aqueous solution containing in each 2 cc. caffeine with sodium benzoate-U. S. P. 0.24 Gm. ($\frac{3}{4}$ grains).

Ampoules Caffeine with Sodium Benzoate-Lakeside, 0.49 Gm. ($\frac{7}{16}$ grains) 2 cc.: An aqueous solution containing in each 2 cc. caffeine with sodium benzoate-U. S. P. 0.49 Gm. ($\frac{7}{16}$ grains).

SATURDAY, JUNE 15, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

THE NEW DIRECTORY

The sixteenth edition of the American Medical Directory,¹ just from the presses and the bindery, contains 195,104 names of physicians, or an increase of 6,188 over the 1938 volume. Because of death, 7,586 names were dropped from the book; the names of 13,798 physicians, new graduates and physicians coming from foreign countries, have been added. Thirty-eight states and the District of Columbia show an increase in the number of physicians.

Refugee physicians seem to account for most of the increase in the Seaboard states. New York leads the list with a gain of 1,783, New Jersey 380, Massachusetts 361 and Pennsylvania 324. California shows a gain of

631 while Florida, the other winter resort state, has a gain of 204. Louisiana shows a notable increase of 264, due perhaps to the establishment of the Louisiana State University Medical Center. Next is Illinois with an increase of 246, just slightly less than the 1938 increase. The other Midwestern states also show increases slightly below those of 1938: Michigan 220 as compared with 277 in the previous edition; Ohio 201 against 210; Minnesota 101 against 143. Iowa, Kansas, Missouri and Nebraska continue their losses in the number of physicians, although the decreases are less than in previous years, possibly an indication that to some degree the rural sections are slowly recovering from the havoc wrought by the dust storms. The Southern states have shown a decrease in the number of physicians in each succeeding Directory. The decrease is now less than in former years. Alabama, Georgia and Mississippi have indicated a steady loss in each edition of the Directory since 1918 and have now gained three, sixty-nine and two physicians respectively, while Tennessee reduced its loss from twenty-two in 1938 to nine in 1940.

Included in this veritable storehouse of useful and dependable information that is the American Medical Directory are extensive data concerning the American Medical Association, its officers, constitution, by-laws, past presidents and the date and place of each meeting. The histories of 456 medical schools, including eighty-seven approved schools and schools of the basic medical sciences now in existence in the United States and Canada, are provided; the essentials of an acceptable medical school and the lists of graduate and foreign medical schools are also included. Also compiled by the Council on Medical Education and Hospitals is a list of hospitals approved for training interns as well as those approved for fellowships and residencies.

Prominent mention is given to the various examining boards in medical specialties now functioning. A brief history and the names of the officers of the various boards are given in the preliminary section. Symbols indicating certification by these boards appear in the data of more than 14,000 physicians in the body of the book.

As in previous editions, lists of medical journals, medical libraries, members of special medical societies, medical officers of the United States Army, United States Navy, United States Public Health Service, Veterans Administration and Indian Field Service are presented in the front section of the book.

In the main section of the Directory physicians are grouped by cities, in strict alphabetic order for each state. Published under each state are the medical practice acts, members of boards of medical examiners, state boards of health, county and city health officers and the officers of state and county medical societies.

¹ American Medical Directory. Sixteenth edition. Cloth. Price, \$18. Pp. 2,683. Chicago: American Medical Association, 1940.

Following this information is a list of hospitals and sanatoriums, with data regarding bed capacity, type of patients treated and the name of the superintendent. Each physician is biographically described—the year of his birth; his school and year of graduation; his state license; notation if he is a diplomate of the National Board of Medical Examiners and if he has been certified by one of the examining boards in medical specialties; membership in the American Medical Association; his affiliation with a special society; his military title or medical school professorship; his home and office addresses and his office hours. Even without the address of the physician he can be readily located in the complete alphabetic index, where all physicians are listed by name in alphabetic order followed by the city in which the physician is located.

To general practitioners, specialists, hospitals, medical libraries, insurance companies and industrial concerns, this directory is invaluable, paying for itself many times by saving time, trouble and confusion.

To the secretaries of the various medical examining boards of the United States and Canada, to the deans of medical schools, to the officers of the constituent state associations and component societies, to the various health authorities and to the thousands of physicians and correspondents who have so willingly assisted in making possible this edition—we extend our thanks and express our appreciation.

TUBERCULOUS BACILLURIA

Can tubercle bacilli pass through a normal kidney? This question involves the larger question of physiologic excretion of bacteria through normal kidneys. The experimental studies of Wyssokowitsch and the microscopic studies of Opitz, von Klecki and Koch demonstrate that bacteria injected into the blood stream rapidly disappear from the circulation. They tend to pass through the circulation of the kidneys to lodge in other organs, such as the liver, the spleen, the lungs and the bone marrow, where they are subsequently destroyed by the tissue cells. This, and not excretion by the kidneys, appears to be the main defense mechanism of the body in cases of blood stream infection. The more specific question as to whether or not a normal kidney can excrete tubercle bacilli has an important epidemiologic aspect and, in a narrower sense, a diagnostic significance. It would seem inadvisable to accept unqualifiedly the dictum of Casper and of Israel that the presence of tubercle bacilli in the urine indicates invariably tuberculosis of the kidney.

Foulerton and Hillier¹ were the first to report on tuberculous bacilluria in the absence of any evidence

of tuberculosis in the kidney. They demonstrated by animal inoculation the presence of tubercle bacilli in the urine of nine of eighteen patients suffering from chronic advanced pulmonary tuberculosis. Postmortem examinations were made in six of the positive cases and the kidneys on gross examination failed to exhibit tuberculous lesions. The report did not contain a microscopic study nor was the condition of the genitalia investigated. The numerous investigations that have followed the work of the English authors have given rise to three theories: (1) The normal kidney is permeable to tubercle bacilli, (2) the passage of tubercle bacilli is possible only in the presence of a pathologically altered kidney and (3) tubercle bacilli are capable of setting up in the kidney a nonspecific inflammatory condition, a tuberculous nephritis. According to Wildbolz this represents a special form of reaction on the part of the renal tissue to tubercle bacilli of attenuated virulence. The lesion is capable of healing or of terminating in cicatricial shrinking. Fedorov considered this a pre-tuberculous stage which could lead to the development of a typical tuberculous lesion—so-called excretion tuberculosis. The many sources of error in the solution of this complicated problem called for the application of the most exacting and rigorous scientific criteria. The diversity of opinions had its origin principally in the inadequate and faulty methods of investigation.

Dimitza and Kartal² laid down the following criteria as indispensable for the solution of the problem: 1. The presence of tubercle bacilli in separated kidney urine must be demonstrated by animal inoculation and by culture. 2. One must prove that the bacilli came from the kidney: the possible contamination with tubercle bacilli from the genitalia in man must be ruled out by a complete urologic examination. 3. Careful microscopic and bacteriologic examinations of the kidney, employing the study of serial sections must be made.

Kielleuthner did not find tubercle bacilli in the urine of nineteen patients with advanced pulmonary tuberculosis and normal urine, while tubercle bacilli were found in three of a group of eighteen patients who exhibited albuminuria. The kidneys of these three patients did not show tuberculous lesions. Kielleuthner concluded that a nontuberculous but pathologic kidney was capable of excreting tubercle bacilli. He did not, however, stain the renal sections for tubercle bacilli nor did he inoculate renal tissue into animals.

In a careful study of 225 cases with extragenital tuberculosis, Dimitza and Schaffhauser,³ of the Clairmont clinic, found tubercle bacilli in the urine of eight

2. Dimitza, A., and Kartal, S.: Kritische Betrachtungen des bisher erschienenen Schrifttum über die Tuberkelbacillurie, *Ztschr. f. urol. Chir.* 35:416 (Nov.) 1932.

3. Dimitza, A., and Schaffhauser, F.: Tuberkelbacillurie und initiale chronische Nierentuberkulose, zugleich ein Beitrag zur Früh-diagnose der chronischen, käsigen Nierentuberkulose, *Ztschr. f. urol. Chir.* 35:440 (Nov.) 1932.

patients. Nephrectomy was performed on all of these. Microscopic studies demonstrated the existence of caseous, cavitating lesions in each case. The authors concluded that the presence of tubercle bacilli in kidney urine indicates the existence of a tuberculous lesion in the kidney. They emphasized, however, that the lesion may be minute and require a painstaking study of serial sections.

Lieberthal and von Húth⁴ injected tubercle bacilli into the ear vein or into the left ventricle of female rabbits. The urine was collected for twenty days and was centrifuged and cultured for tubercle bacilli according to the method of Loewenstein-Sumyoshi on the egg medium of Hohn. Careful microscopic studies demonstrated that a physiologic excretion of bacteria by the kidneys does not occur, that tubercle bacilli do not pass through the kidneys from the blood into the urine because of the comparatively mild immediate action of that organism on the renal tissue, and that previously induced degenerative or inflammatory lesions of the kidneys do not make that organ permeable for tubercle bacilli. The same authors⁵ report the results of a histopathologic examination of 240 tuberculous kidneys from the clinic of von Illyés. They state that in every case in which tubercle bacilli were demonstrated in the separated urine an ulcerated, caseous tuberculous focus was found in the corresponding kidney (usually on the renal papilla). The caseous center of such lesions usually contained numerous tubercle bacilli, which were readily demonstrable by Ziehl-Neelsen staining of serial sections of the ulcer. The authors were convinced that tubercle bacilli alone in the separated urine, even in the absence of pus and a functional defect, indicated the presence of a tuberculous focus in the kidney.

The possibility of a transient tuberculous bacilluria is suggested by Medlar's postmortem studies, in which he found healed, fibrous, cortical lesions in the kidneys of patients with chronic pulmonary tuberculosis and no suggestion of genito-urinary disease during life. His results are not altogether convincing, since he did not establish that the patients excreted tubercle bacilli at any time.

Wildbolz,⁶ in a recent review, says that one could not, on purely theoretical grounds, deny the possibility of healing of tuberculous cortical lesions with a tendency to fibrosis. To prove it, however, would require a combination of a clinical and pathologic investigation. Until such a demonstration is forthcoming, one would be safer in regarding tuberculous bacilluria unaccompanied by pyuria and loss of renal function as the earliest sign of renal tuberculosis.

CRYMOTHERAPY

Medicine owes its progress in part to the curiosity that constantly stimulates the search for new weapons with which to combat well known diseases or their newer pathologic variations. Among the methods which challenge scientific inquiry is the use of general and local refrigeration and its effects on tumor formations and the relief from pain. An experiment¹ recently conducted in Lenox Hill Hospital, New York, was inspired by the "artificial hibernation treatment" originated by Temple Fay and his associates of Temple University Medical School.² The Philadelphia investigators applied the technic to cancer patients in whom unconsciousness or semiconsciousness had been artificially induced in order to assuage pain. Fay and Smith had been able to refrigerate patients from 10 to 18 degrees below normal for periods varying from a few hours to as many as five days.

In the Lenox Hill Hospital experiment a room with a capacity of two beds was constructed, specially equipped, thermostatically controlled and, by air conditioning, maintained at a temperature of 55 F. The crymotherapeutic experiment lasted four months and was performed on twenty-seven patients. Proper instructions were given in advance to the intern and nursing personnel in the clinical and technical details to be employed. Precautions were taken to protect the nurses against undue or prolonged exposure to cold. Facilities for prompt telephonic communication with resident physicians were available. Selection of the patients was based on their fair general condition, if able to be up and about, or, if bedridden, on the presence of intractable pain or large measurable tumor masses. Most of the patients (twenty-two) presented different forms of grave carcinoma, such as carcinoma of the prostate, bladder, heart, cervix, thyroid and colon.

In the procedure followed the patient received chloral and bromides the night before and phenobarbital in the morning. A Levine or Einhorn tube was passed into the stomach and the patient rendered unconscious by rectal and intravenous injections of two generally known anesthetics. He was then brought into the room and placed naked on a bed. The thermocouple was inserted into the rectum, a rubber-covered wire cable leading from the patient's rectum to the recording dial on the wall. The wrists and ankles were tethered with padded restraining loops. The patient's trunk, from the shoulders to half way down the thighs, was then packed with loose ice of the size of nut coal. This ice pack was maintained until the rectal temperature reached 90 F.

L.; Kenyon, Herbert R.; Dixon, John F.; Huber, Frank; Paltauf, Rudolf M.; Sauer, Paul Kurt, and Whittemore, Laurence W.: General Crymotherapy: A Symposium, *Bull. New York Acad. Med.* 16: 312 (May) 1940.

2. Fay, Temple, and Henny, George C.: Symposium on Cancer: Correlation of Body Segmental Temperature and Its Relation to the Location of Carcinomatous Metastasis, *Surg., Gynec. & Obst.* 66: 512 (Feb., No. 2A) 1938. Smith, L. W., and Fay, Temple: Temperature Factors in Cancer and Embryonal Cell Growth, *J. A. M. A.* 113: 653 (Aug. 19) 1939.

(a process requiring usually from one and one half to two and one half hours). It was then removed and the patient dried. At a room temperature of 55 F. the patient's rectal temperature would go down to 80 F. Normal temperatures were kept between 80 and 85 F. If the temperature became too low, blankets and lukewarm water bags were used. If the temperature rose, ice bags without cloth coverings were applied to the trunk and upper thighs. The temperature, pulse, respiration and blood pressure were charted every half hour. Through a stomach tube a dose of 2 ounces (60 cc.) of physiologic solution of sodium chloride with a 10 per cent dextrose solution was instilled every hour. For restlessness, sodium amytal or soluble phenobarbital was usually given in suitable quantities. Twice a day the stomach was siphoned empty. Once a day the stomach was lavaged with a quart (liter) of physiologic solution of sodium chloride, a pint at a time. When treatment was to be discontinued, the air conditioning apparatus was shut off and the room allowed to return to normal temperature. The patient was covered with blankets and the body slowly restored to the normal temperature. This required from six to eight hours. Not until then was the patient returned to the ward. Inductions could be repeated five times or more, depending on the patient's general condition.

The authors report that in eleven of seventeen cases of intractable pain due to carcinoma there was sufficient alleviation of pain to obviate the necessity of administering narcotics for variable periods. In one case of prostatic carcinoma the patient had been unable to lie on his back for more than a few minutes at a time. After the first session in cryotherapy he was able to do so without large doses of morphine and cobra venom. In some cases there was little or no relief from pain. Eventually pain recurred in all cases, in some as early as twenty-four hours after treatments were discontinued. Once relief lasted as long as eight weeks. Recurrence of pain and progress of cachexia may be due to the fact that the intervals between treatments were too long. Regression of primary tumors or metastases was not observed, nor could unusual cell alterations or changes attributable to the effect of the treatment on neoplastic tissue be demonstrated. Roentgenoscopy of bone metastases in two cases showed a definite increase. The presence of pulmonary metastases seemed to predispose to pulmonary complications, though otherwise risks from pneumonia and nephritis were not as great as expected. Neurologic observations after the treatment did not differ from the neurologic status before. Thirteen of the twenty-seven patients died subsequently, within six to forty-six days after their last induction, from a variety of causes.

The authors suggest the extension of cryotherapeutic experimentation to other diseases, such as Hodgkin's disease, venereal lymphogranuloma and subacute bacterial endocarditis. A patient with noncarcinomatous drug addiction, who had taken from 6 to 8 grains

(0.4 to 0.5 Gm.) of morphine daily for at least fifteen years, after five days of the treatment lost her craving for the narcotic and experienced her first normal menstruation in seven years. Local cryotherapy was performed in too limited a degree to warrant conclusions as to its merits. Vaughn,³ in a recent report on cryotherapy applied to six patients with hopeless metastatic carcinoma, found that relief of pain was "the only result of possible value" achieved. He regards the procedure as hazardous and not justifiable in the treatment of advanced metastatic carcinoma.

In general, these results seem to promise little or nothing for this method as a general treatment for carcinoma. Nevertheless the therapeutic uses of cold may be considerable. Such biologic investigations as have been recorded have added greatly to scientific knowledge of the effects of cold on living tissue.

Current Comment

HYPERTENSION AND THE THIOCYANATES

As early as 1903 it was known that the continued administration of the thiocyanates is often effective in reducing hypertension. Because of toxic reactions, interest in the therapy was not strong until 1925, when Westphal reintroduced the subject. Although some investigators have felt them to be of value, others have regarded them as useless and dangerous. In 1929 the Council on Pharmacy and Chemistry reported the evidence for the value of the thiocyanates to be far from conclusive; moreover, their use seemed to be definitely contraindicated in acute inflammation of all types, in nephritis and in severe renal insufficiency. In many cases of hypertension the production of lowered pressures does more harm than good. Since that report, the Council's attention has been drawn to such toxic reactions as cutaneous eruptions, vertigo, gastrointestinal upsets, weakness of the arms and legs and mental manifestations. A recent communication¹ revealed eight fatalities reported as following the intake of thiocyanate. Hamilton² studied the blood pressures of street dogs and reported a significant lowering of pressure in the hot summer weather and higher values in the winter. Administration of sodium thiocyanate to dogs with the highest values resulted in a fall in pressure, but the fall was of no greater magnitude than that which naturally occurred with the season of the year. He concluded that the thiocyanate did not produce a significant permanent lowering of blood pressure in hypertensive dogs. In view of the results of these workers, the value of sodium or potassium thiocyanate, in the light of its dangerous possibilities, seems more doubtful than ever.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

District Meetings.—The Third Councilor District Medical Society met at Brinkley, May 16. Among the speakers were Drs. Herbert Fay H. Jones, Little Rock, on "Treatment of Specific Urethritis"; Lucius Carl Sanders, Memphis, Tenn., "Heart Disease"; Joseph F. Shuffield, Little Rock, "Treatment of Colles' Fracture," and Frank Thomas Mitchell, Memphis, Tenn., "Intestinal Disorders in Children."—The Fifth Councilor District Medical Society was addressed at Waldo, May 14, by Drs. William Hibbitts, on "Significance of Early Recognition of Acute Abdominal Emergencies"; Chester E. Kitchens, "Sulfapyridine and Sulfanilamide, Their Uses in Diseases of Children," and Theron E. Fuller, "Some Eye, Ear, Nose and Throat Topics of Interest to the General Practitioner." All were from Texarkana.—The Second District Medical Society was addressed in Batesville, April 8, by Drs. Henry V. Stewart, Little Rock, "Laboratory Service in Preventive Medicine"; George V. Lewis, Little Rock, "Management of Hyperthyroidism," and Wayne M. Hull, Oklahoma City, "Inhalation Therapy."

CALIFORNIA

State Medical Election.—Dr. Henry S. Rogers, Petaluma, was named president-elect of the California Medical Association at its recent annual meeting in Coronado, and Dr. Harry H. Wilson, Los Angeles, was installed as president. The next annual meeting will be in Del Monte.

Forty Years as Chief Surgeon.—Dr. Oliver D. Hamlin, since 1900 chief surgeon at the Alameda County Receiving Hospital, retired May 20. Dr. Hamlin graduated at the Cooper Medical College, San Francisco, in 1894. He has served as president of the Alameda County Medical Association and of the California Medical Association and for six terms was a member of the House of Delegates of the American Medical Association.

New Trudeau Society.—The California Trudeau Society was organized in Santa Barbara, April 13, with the following officers: Drs. Buford H. Wardrip, San Jose, president; Reginald H. Smart, Los Angeles, president-elect; William L. Rogers, San Francisco, vice president; Emil Bogen, Olive View, secretary-treasurer. William Ford Higby is executive secretary. The society, which is composed of physicians interested in tuberculosis, it is proposed, will be responsible for the medical portion of the programs for annual meetings of the California Tuberculosis Association.

DISTRICT OF COLUMBIA

Annual Extension Course.—The fifth annual alumni extension course of Georgetown University School of Medicine, Washington, was conducted June 7-8. Among the speakers were:

- Dr. Philip A. Caulfield, Infections of the Hand.
- Drs. William J. Cusack and Fred O. Coe, Abdominal Pregnancies with Successful Termination (2 Cases).
- Dr. Antoine Schneider, Differentiation and Interrelationship of the Organic, the Functional and Malingering in Neuropsychiatry.
- Dr. Frank J. Eichenlaub, Common Skin Diseases and Their Office Treatment: Illustrated with Colored Lantern Slides from the Collection of Dr. Robert Stolar.
- Dr. William B. Porter, Richmond, Va., Relationship of Nutritional Deficiency to the Clinical Course of Cardiovascular Disease.
- Dr. Lloyd G. Lewis, Baltimore, Arterial Hypertension from the Urologic Standpoint.

IDAHO

Hospital News.—The new Grangeville Hospital, costing about \$60,000, was opened for use April 15; it has a bed capacity of twenty-five.—A forty bed addition is being planned for St. Anthony Mercy Hospital, Pocatello, at a cost of \$75,000; it will increase the capacity to 100 beds.

Annual Registration Due July 1.—All practitioners of medicine and surgery holding licenses to practice in Idaho are required by law to register annually on July 1, with the Department of Law Enforcement, and at that time to pay a fee of \$2. If a licensee has not paid the annual registration fee by October 1, his license can be canceled but will be restored within five years thereafter on payment of the delinquent fees and a \$10 penalty. If a license has been canceled for more than five years, it can be reinstated only on the payment of \$25 and on the licensee's passing an examination, the nature of which shall be determined by the Department of Law Enforcement.

INDIANA

Annual Postgraduate Course.—The eighth annual postgraduate course of Indiana University School of Medicine, Indianapolis, was held May 6-11. In addition to clinics and pathologic conferences the program covered a wide range of subjects, including "Radiculitis and Nucleus Pulposus in Relation to Back Pain"; "Quantitative Assay of Estrogens in Normal and Abnormal Menstrual Cycles"; "Is Acute Bowel Obstruction a Surgical Emergency?"; "Proper Surgical Management of Empyema," and "Deficiencies in or from Intestinal Dysfunction." Participating in the course were: Drs. Roy D. McClure and Frank W. Hartman, Detroit; William D. Stroud, Philadelphia; Edward L. Compere, Chicago; Paul W. Harrison, medical missionary, Arabia, and Bryng Bryngelson, Ph.D., Minneapolis. A round table on pediatrics was conducted by Drs. Stanley Gibson, Chicago, and Abraham B. Schwartz, Milwaukee, in collaboration with the Indiana Pediatric Society.

Dean Myers Retires at Bloomington.—Dr. Burton D. Myers, dean of the Indiana University School of Medicine at Bloomington, announces his retirement at the end of the current semester. He has been affiliated with the school since 1903, when he was made professor of anatomy. He was made assistant dean of the school in 1920 and dean in 1927. A native of Ohio, Dr. Myers received his medical degree from the University of Leipzig in 1902. He was superintendent of the Greenwich, Ohio, schools in 1893; assistant in physiology at Cornell University College of Medicine from 1898 to 1900, and assistant in anatomy at Johns Hopkins University School of Medicine 1902-1903. He was president of the Association of American Medical Colleges in 1928. Announcement was made of the retirement of the following part time members of the medical and dental faculty of the university: Dr. Alois B. Graham, chairman of the division of gastro-enterology and professor of surgery; Dr. Charles E. Cottingham, associate in neurology and psychiatry; Dr. John Tipton Wheeler, professor of anatomy at the dental school, and Dr. Louis DeKeyser Belden, associate professor of pathology, bacteriology and histology.

KENTUCKY

Society Elects Secretary for Life.—Dr. Herbert H. Hunt, Mayfield, was elected secretary-treasurer of the Graves County Medical Society for life at its annual meeting recently. He has held the office for the past thirty-six years.

New Health Officers.—Dr. Herman T. Carter, Edmonton, has been appointed director of a two county health unit for Green and Metcalfe counties.—Dr. Wallace Byrd, recently of Manchester, has been appointed health officer of Owen County to succeed Dr. Price Sewell Jr., now of Fayette County.—Dr. James W. Scudder, Carlisle, has resigned as health officer of Nicholas County.—Dr. Edward C. Humphrey, Somerset, has resigned as health officer of Pulaski County to accept a similar position in Mercer County. Dr. Mildred E. Burton, formerly of Berea, will succeed him in Pulaski.

LOUISIANA

Special Society Elections.—Dr. Herman Aubrey White, Alexandria, was elected president of the Louisiana State Pediatric Society at its twelfth annual meeting in New Orleans, April 22; Dr. Julian Graubarth, New Orleans, vice president, and Dr. William C. Rivenbark, New Orleans, secretary-treasurer.—Dr. Phillips J. Carter, New Orleans, was chosen president of the Louisiana Gynecological and Obstetrical Society at its annual meeting, April 20, in New Orleans.

Society News.—The Ouachita Parish Medical Society was addressed, April 4, by Dr. James Q. Graves, Monroe, on "The Drainage and Treatment of Appendiceal Abscess."—A symposium on geriatrics was presented before the Orleans Parish Medical Society, New Orleans, April 8, by Drs. Isidore L. Robbins, Theodore A. Watters, Allan C. Eustis and Isidore Cohn. Hymen S. Mayerson, Ph.D., presented a biographic sketch of Bennett Dowler, New Orleans physiologist, 1797-1879.

MASSACHUSETTS

Five Year Grant for Teaching and Research.—Under a five year grant for teaching and research in neurology from the Rockefeller Foundation to Tufts College Medical School, Dr. Kurt Goldstein, clinical professor of neurology, Columbia University College of Physicians and Surgeons, has been appointed to a similar position at Tufts.

Society News.—Dr. Roy D. Halloran, Waltham, was elected president of the New England Society of Psychiatry at its annual meeting in Hathorne, April 25; Dr. George E. McPherson, Belchertown, vice president, and Dr. Bardwell H. Flower, Boston, secretary-treasurer. —At a meeting of the New England Dermatological Society in Boston, April 10, Dr. Alan R. Moritz spoke on "Accident, Murder or Suicide?" —The New England Oto-Laryngological Society was addressed, April 10, among others, by Dr. Herman A. Winkler, Providence, R. I., on "Acute Surgical Mastoiditis Following Fracture of the Skull"; Warren E. Kershner, Bath, Maine, "Bronchial Asthma Due to Bacterial Allergy," and Adolphe J. Provost, Manchester, N. H., "Osteomyelitis of the Frontal Bone."

Personal.—Dr. Charles L. Clay has resigned as superintendent of Long Island Hospital, Boston, to accept a similar position at the Jackson Memorial Hospital, Miami, Fla. —Dr. Joseph E. Canby, Great Barrington, has been appointed medical examiner of the southern Berkshire area, newspapers reported, succeeding Dr. John B. Beebe, who has retired and is living in Florida. The area includes all towns from Stockbridge to the Connecticut line and west to the New York State line.

MICHIGAN

Society News.—Dr. Andrew H. Dowdy, Rochester, N. Y., addressed the Ingham County Medical Society in Lansing, April 16, on "The Role of X-Ray and Radium Therapy in the Control of Cancer and Allied Diseases." Dr. Henry M. Goodyear, Cincinnati, discussed "Practical and Helpful Hints to the General Practitioner in the Diagnosis and Treatment of Ear, Nose and Throat Conditions" before the Ingham County Medical Society in Lansing, May 2. —Dr. Gordon B. Myers, Detroit, addressed the Muskegon County Medical Society in Muskegon, April 19, on "Diseases of the Liver."

Special Society Elections.—Dr. George J. Curry, Flint, was chosen president-elect of the Michigan Association of Industrial Physicians and Surgeons at its recent annual convention in Grand Rapids, and Dr. Frank T. McCormick, Detroit, was installed as president. Other officers are Drs. Corydon L. F. DeVries, Lansing, vice president, and J. Duane Miller, Grand Rapids, secretary-treasurer. —Dr. James H. Dempster, Detroit, was recently elected president of the Michigan Association of Roentgenologists; Dr. Leland E. Holly, Muskegon, vice president, and Dr. James E. Lofstrom, Detroit, secretary-treasurer.

Plans for Medical Center in Detroit.—Plans for a \$50,000,000 program to build and operate a medical educational center in Detroit were announced, May 20, by Dr. Edgar H. Norris, dean of Wayne University College of Medicine, at the annual meeting of the Wayne County Medical Society. A group of doctors has been studying the plans which have received the endorsement of the Detroit Board of Education, the council of the medical society, officers of the university, trustees of the Wayne University Foundation and the advisory council of the medical school faculty. Four or five city blocks would be set aside for the center, forming the site for eight buildings at an estimated cost of between \$10,000,000 and \$12,000,000. The program proposes to raise \$50,000,000 from donors, the major portion to be used to support the work of the center, for research and for the personnel of the faculty. Maintenance would be left to the board of education, and the present budget of the medical school would be sufficient for permanent maintenance of the campus and its buildings, Dr. Norris said. The Wayne University Foundation was organized in 1938 to receive, manage and disburse grants and gifts to Wayne University and to promote scientific research and investigation.

MISSOURI

Annual Trudeau Lectures.—The annual lectures sponsored by the St. Louis Trudeau Club were delivered, April 23, by Drs. Hyman I. Spector and Everts A. Graham, St. Louis. Their subjects were "Differential Diagnosis in Hemorrhage from the Lung" and "Surgical Aspects of Hemorrhage from the Lung" respectively.

Million Dollar Cancer Hospital Dedicated.—The Ellis Fischel State Cancer Hospital at Columbia was officially opened, April 26. The hospital represents an investment of nearly \$1,000,000 and is said to be the "first hospital ever established by a state for the exclusive care of cancer sufferers." The PWA contributed about 45 per cent of the total cost. The seven story building has a capacity of eighty-five beds. The first floor contains administrative offices, diagnostic clinic and the high voltage x-ray therapy department. The second, third and fourth floors contain beds for patients. On the fifth floor are quarters for residents, the library and conference rooms. The operating rooms and the diagnostic x-ray department are on the sixth floor, while laboratories are located on the seventh floor. The kitchen, dining rooms, laundry and boiler rooms are in the basement. A total of 550 mg. of radium, representing an approximate value of \$16,500, and x-ray equipment costing \$27,717 will be available for the treatment of patients. There is a probability that an additional 150 mg. of radium will be available at the hospital later. The National Cancer Institute has made possible a considerable portion of the radium supply. Plans for the hospital were given legislative momentum in Jefferson City in 1937. The bill, which was passed in that year, provided for the erection of the hospital and called for the formation of a cancer commission and for the establishment of diagnostic clinics. Dr. Ellis Fischel, for whom the hospital is named, became the first chairman of the commission, and after he was killed in an automobile accident May 14, 1938, while driving to Jefferson City on commission business the chairmanship was taken over by Frank T. Hodgdon,

State owned cancer hospital.

banker, Hannibal. Other members of the commission are Dr. Frederick J. Taussig, vice chairman, St. Louis; and Dr. Paul F. Cole, Springfield, and William M. Clark, business executive of St. Joseph. Miss Dorothy A. Helmann is executive secretary. The commission has offices at 3713 Washington Boulevard, St. Louis. The hospital will be governed and maintained by the commission. Columbia was considered an ideal site because it is virtually in the heart of the state. Originally, the 40 acre tract of land for the hospital was outside the city limits of Columbia, but in order to provide ultimate protection for the institution the city boundaries were extended to assure the use of Columbia's utilities such as light, water, fire protection and so on. No patient will be admitted by merely applying at the hospital. First he must obtain an application blank prepared by the commission. This blank is composed of three sections, the first certifying to the indigency of the patient, the second giving information on the patient's physical condition by a physician appointed by the county court of residence of the patient. If the court, on reviewing the application, is convinced that the patient is indigent and might be suffering from cancer, it will ask the hospital to admit the patient. The only charge to the county is \$5 per month per patient. There is no charge to the patient.

NEBRASKA

Society News.—Drs. Edwin Davis and John E. Courtney, Omaha, addressed the Omaha-Douglas County Medical Society, Omaha, May 14, on "Facts and Fancies Relating to the Etiology of Bladder Tumors" and "Gastrostomy" respectively. Dr. Walter C. Alvarez, Rochester, Minn., addressed the society recently on "The Ever Present Complaint: Indigestion, Its Significance and Its Management." Dr. Dean M. Lierle, Iowa City, addressed the society, April 9, on "Clinical Significance of Hoarseness." —Drs. John C. Peterson and James M. Woodward addressed the Lancaster County Medical Society,

Lincoln, recently, on "The Eye and Ear as Etiological Factors in Headache."—Drs. Osgoode S. Philpott and Constantine F. Kemper, Denver, addressed the Southwest Nebraska Medical Society, McCook, recently, on "Diagnosis and Management of Common Dermatological Conditions" and "Newer Procedures in the Practice of Endocrinology" respectively.—Dr. Foster L. Matchett, Denver, discussed fractures at a meeting of the Garden-Keith-Perkins County Medical Society in Ogallala, April 10.—At a meeting of the Adams County Medical Society in Ingleside, April 3, Dr. Donaldson W. Kingsley, Hastings, spoke on "Care and Treatment of Hip Fractures" and Mr. James D. Conway on legal aspects of medicine.

NEW YORK

New Health Officers.—Dr. Wilfred L. J. McDonald, Glens Falls, formerly an assistant district health officer, has been appointed health commissioner of Columbia County, effective April 1. Dr. Robert C. Hume, Olean, recently on the staff of the Cattaraugus County health department, has been appointed an assistant district health officer.

Conference of Health Officers and Public Health Nurses.—The annual Conference of Health Officers and Public Health Nurses will be held at the Grand Union Hotel, Saratoga Springs, June 25-27. Addresses at the opening session will be delivered by Governor Herbert H. Lehman, Dr. Edward S. Godfrey Jr., state health commissioner, and Dr. Thomas Parran, surgeon general, U. S. Public Health Service. Other speakers on the program will include:

Dr. Nathan B. Van Etten, New York.

Dr. Frank G. Boudreau, New York, Nutrition: The Next Step in Public Health.

Arthur H. Merritt, D.D.S., New York, Dentistry and Public Health.

Dr. Francis F. Schwentker, New York, Some Aspects of Scarlet Fever in Rumania.

Dr. John Rodman Paul, New Haven, Conn., Some Public Health Considerations of Rheumatic Fever and Rheumatic Heart Disease.

Dr. James A. Crabtree, Washington, D. C., Epidemiology of Cancer.

Dr. Don W. Gudakunst, New York, A Review of the Treatment and Prevention of Infantile Paralysis.

The public health nurses' meeting will feature a symposium on "keeping up with public health nursing."

New York City

Class of 1915 Scholarship Fund.—At the twenty-fifth anniversary of the graduation dinner of the class of 1915, New York University College of Medicine, May 11, the seventy-two physicians in attendance pledged that a scholarship fund will be raised annually to be donated to the medical college. It will be known as "The Class of 1915 Scholarship Fund." Contributions to this fund by members of the class may be mailed to Dr. Henry M. Scheer, 522 West End Avenue.

Physician Honored as Athletic Director.—Dr. John Brown Jr. was guest of honor at a recognition dinner, May 13, marking his retirement as physical director of the National Council, Y. M. C. A. Dr. Brown began his career with the "Y" in Toronto in 1897 as assistant physical director. His first post in the United States was in Mount Vernon, N. Y., in 1902. He was granted a commission of honorary major by the British War Office in London in 1917 in recognition of services to enlisted men in Canada and overseas; was appointed by President Coolidge as one of four delegates to represent the United States at the International Congress on Hygiene at Prague in 1925; was a member of President Hoover's White House Conference on Child Health in 1931 and was elected a "Fellow of International Scientific Association for Physical Culture at Berlin, 1936." Dr. Brown graduated at the University and Bellevue Hospital Medical College, New York, in 1910.

Society News.—Drs. Emery A. Rovenstine and Alvan L. Barach addressed the Medical Society of the County of New York, May 27, on "The Selection of a General Anesthetic" and "Oxygen Therapy and Helium-Oxygen Therapy: Recent Methods and Results in Clinical Medicine" respectively.—Drs. Thomas T. Mackie and Bret Ratner addressed the New York Physicians-Yorkville Medical Society, May 22, on "The Problem of Vitamin Deficiencies in the Adult" and "The Problem of Food Allergy in Childhood" respectively.—Speakers at a meeting of the New York Endocrinological Society, May 22, were Drs. George B. Dorff and Louis J. Soffer, on "Hormonal Therapy for Hirsutism" and "Modern Treatment of Addison's Disease" respectively.—Dr. Benjamin Jablons addressed the Medical Society of the County of Queens, May 28, on "Diseases of the Peripheral Vascular System."—Drs. Priscilla White and Alexander Marble, Boston, addressed the

Medical Society of the County of Kings, May 21, on "Diabetes in General and in Relation to Pregnancy" and "Diabetes in Relation to Surgery" respectively.—At a meeting of the Brooklyn Thoracic Society, May 17, the speakers included Strashimer A. Petroff, Ph.D., on "Bacteriology of Mixed Infection in Pulmonary Tuberculosis" and Dr. Monroe E. Greenberger, "Management of Urinary Tuberculosis."—Dr. James B. Collip, Montreal, Canada, addressed the anniversary meeting of the International Spanish Speaking Association of Physicians, April 15, on "The Pituitary Gland and Diabetes."

OHIO

Personal.—Members of the staff of St. Elizabeth Hospital, Dayton, who have served twenty-five years or more were honored at a testimonial dinner recently. The guests of honor were Drs. Roy S. Binkley, Gustav A. Hochwalt, John W. Millette, William H. Delscamp, Silas E. Hendren, Clement D. Smith, Curtiss Ginn, Arthur W. Carley, Wilson G. Claggett, John K. Larkin and O. B. Kneisley, D.D.S.—Dr. George H. Bradley, Cincinnati, recently retired after forty-five years in charge of the first aid unit of the Cincinnati Post Office.—Dr. and Mrs. Robert J. Baird, Creston, recently celebrated their sixty-fifth wedding anniversary.

Society News.—Dr. Edgar V. Allen, Rochester, Minn., addressed the Summit County Medical Society, Akron, April 2, on "Peripheral Vascular Diseases."—Dr. Willis S. Peck, Toledo, addressed the Academy of Medicine of Toledo and Lucas County, April 19, on "Roentgen Diagnosis of Some Common Chest Lesions."—Dr. Edwin J. Stedem, Columbus, discussed "Bleeding from the Uterus" at a meeting of the Montgomery County Medical Society, Dayton, April 19.—Dr. Harry Eagle, Baltimore, addressed the Academy of Medicine of Cincinnati, April 2, on "Practical Aspect of Current Investigative Studies in Syphilis." Dr. Francis E. Seneac, Chicago, was the speaker, April 9, on "Differential Diagnosis of Recurrent Skin Eruptions of the Hands and Feet." Dr. Lawrence W. Smith, Philadelphia, spoke, April 23, on "Human Refrigeration."

OREGON

Meeting of Health Officers.—The annual meeting of health officers and sanitarians of Oregon was held at Astoria and Seaside, May 23-25. Among other features was a symposium on communicable diseases, with Drs. Grover C. Belinger, Salem, speaking on tuberculosis; John G. Strohm, Portland, gonorrhea, and William Levin, D.P.H., Portland, laboratory advances on typhoid.

Professorship of Surgery Established.—The income from a recent bequest of \$250,000 to the University of Oregon, Portland, will be used to establish a Kenneth A. J. Mackenzie professorship in surgery at the medical school, according to *Northwest Medicine*. Dr. Mackenzie was a member of the faculty from 1887 until his death in 1920, first as professor of the theory and practice of medicine and later as professor of operative and clinical surgery. He was also dean of the medical faculty from 1912 until his death. The new fund also includes an annual memorial fellowship of \$1,000 for premedical students.

PENNSYLVANIA

District Meeting.—The Seventh Councilor District of the Medical Society of the State of Pennsylvania held a meeting in Williamsport, April 12. The speakers included Drs. Emanuel Libman, New York, on "Observations on Abdominal Diagnosis with Special Reference to Hyposensitive Individuals"; John B. Nutt, Williamsport, "Eclampsia and Its Treatment at Williamsport Hospital," and Herbert T. Kelly, Philadelphia, "Healthful Living." The following officers of the state society made addresses: Drs. Charles H. Henninger, Pittsburgh, president; Francis F. Borzell, Philadelphia, president-elect; Walter F. Donaldson, Pittsburgh, secretary, and David W. Thomas, Lock Haven, past president. Awards to physicians who have been in practice for fifty years were made to Drs. James T. Hurd, Galeton, and Charles E. Heller, Williamsport.

Philadelphia

Annual Lectures at Jewish Hospital.—The following lectures, given recently, made up the 1940 group in a series sponsored annually by the Jewish Hospital: Drs. Isidor S. Ravdin, "The Management of Surgical Jaundice"; Arthur M. Fishberg, New York, "Hypertension and Pregnancy," and Walter I. Lillie, "Fetal Changes Associated with Arterial Hypertension."

MEDICAL NEWS

2395

Foundation to Study Treatment of Cancer.—The Foundation for the Study of Neoplastic Diseases has been created at the University of Pennsylvania Medical School by the Penn Mutual Life Insurance Company. It will be under the immediate direction of Dr. John S. Lockwood, with all chiefs of service in the University Hospital cooperating to coordinate the various units of the hospital. The project will be financed by the Penn Mutual Life Insurance Company for five years.

TEXAS

State Medical Election.—Dr. Neil D. Buie, Marlin, was chosen president-elect of the State Medical Association of Texas at its annual meeting in Dallas, and Dr. Preston Hunt, Texas, was installed as president. Other officers include Drs. George A. Schenewerk, Dallas; James J. Gorman, El Paso, and St. Julien R. Murchison, Fort Worth. Drs. Holman Taylor and Khleber H. Beall, both of Fort Worth, were reelected secretary and treasurer respectively. The 1941 session will be held in Fort Worth.

District Meetings.—The South Texas District Medical Society held its semiannual meeting in Beaumont April 25. Among the speakers were Drs. Samuel R. Snodgrass, Galveston, on "The Encephalogram and Its Abnormalities in Certain Clinical Disorders"; Taylor C. Walker, Beaumont, "Testosterone Propionate and Estrogenic Hormone in Vascular Diseases"; Loring M. Shipp, Henderson, "Acute Appendicitis in Children"; Gibson, Lufkin, "Diagnosis and Treatment of Acute Osteomyelitis." Dr. Leopold H. Reeves, Fort Worth, president of the State Medical Association of Texas, also made an address. The Northwest Texas District Medical Association held a meeting in Fort Worth, April 9. Following an all day scientific program, a banquet was held with the following speakers: Drs. Felix P. Miller, El Paso, on diagnosis of respiratory diseases; Henry R. Hoskins, Sanatorium, diseases of the lungs, and Leopold H. Reeves, Fort Worth, on the program of the state medical association.

VIRGINIA

Regional Meeting.—The South Piedmont Medical Society held its semiannual meeting in Turberville, April 16. A symposium on syphilis was presented by Drs. Walter S. L. McMann and Edwin E. Barksdale, Danville, and Edwin A. Harper, Lynchburg, with discussion by Dr. Thomas W. Murrell, Richmond. Other speakers included Drs. George B. Craddock, Richmond, on "Acute Hemolytic Anemia Occurring During Sulfanilamide Administration," and William H. Higgins, Richmond, "Modern Treatment of Chronic Hypertension."

John Horsley Memorial Prize Awarded.—Dr. Dupont Guerry, on the staff of the Manhattan Eye, Ear and Throat Hospital, New York, has been given the John Horsley Memorial Prize in medicine of \$600, in recognition of his discovery of "the use of vitamin K in stopping excessive bleeding in newborn infants." The work was done in association with Dr. William W. Waddell Jr., associate professor of pediatrics, University of Virginia Department of Medicine, Charlottesville. The fact that he graduated more than fifteen years ago from the medical school made Dr. Waddell ineligible for the prize.

WISCONSIN

University Lectures.—The sixth annual Charles R. Bardeen Memorial Lecture was presented at the University of Wisconsin Medical School, Madison, April 25, by Dr. Francis P. Daly, Chippewa Falls, under the auspices of the Phi Chi fraternity. Dr. Daly's subject was "Medicine as It Was Practiced in Wisconsin in the Horse and Buggy Days."—Paul H. Phillips, Ph.D., assistant professor of biochemistry, University of Wisconsin, addressed the university medical society, April 30, on "The Pathology of Certain Nutritional Deficiencies."

District Meetings.—A meeting of the Thirteenth Councilor District of the State Medical Society of Wisconsin was held in Antigo recently. Dr. William S. Middleton, Madison, spoke on "Coronary Occlusion" and "Bedside Medicine and the Newer Drugs" and Dr. Joseph W. Gale, Madison, on "Diseases of the Breast."—Dr. Frank H. Lahey, Boston, was the guest clinician at a joint meeting of the Third Councilor District Medical Society and the Dane County Medical Society in Madison, May 20. Drs. Ovid O. Meyer and Robert E. Burns, Madison, also participated in the program of dry clinics. In the evening Dr. Lahey was the speaker at a dinner meeting in honor of Dr. Henry V. Bancroft, Blue Mounds, who has completed fifty-five years in practice.

Personal.—Dr. Mariano B. Caballero, San Juan, has been appointed a member of the Board of Medical Examiners of Puerto Rico to succeed Dr. Luis J. Fernandez, San Juan, whose term expired.

PUERTO RICO

Bureau to Promote Health Education.—The Department of Health of Puerto Rico has established a new "bureau of medical education" to assist in educating the population in health matters in connection with the work of the various health units. The department is also cooperating with the School of Tropical Medicine and the University of Puerto Rico in plans for the establishment of a school of public health in San Juan for postgraduate training of public health officials, nurses, sanitary inspectors and laboratory technicians. Dr. Tomas F. Blanco, San Juan, has been placed in charge of the new bureau.

University News.—Recent speakers at the School of Tropical Medicine of the University of Puerto Rico under the auspices of Columbia include the following:
Dr. Jose Nova-Benitez, Acute Appendicitis in the Aged.
Dr. Rafael Rodriguez Molina, Sprue in the Puerto Rican Indigent.
Dr. Juan H. Font, Acute Frontal Sinusitis.
Drs. Luis J. and Ricardo F. Fernandez, Glaucoma, Its Etiology, Pathology and Treatment.
Dr. Jenaro Suarez, Differential Diagnosis and Treatment of Certain Forms of Uterine Hemorrhage.
Dr. Kenneth B. Turner, New York, and Enrique Koppisch, held a clinicopathologic conference at the school, April 28.

Society News.—At a meeting of the Humacao District Medical Society, May 5, the speakers included Drs. Ng William Hing, on "Blood Transfusion and Parenteral Fluid Administration in Pediatrics"; Charles M. Carpenter, Rochester, N. Y., "Diagnosis of Gonococcal Infection"; Eva F. Dodge, Montgomery, Ala., "Newer Aspects of Nutrition During Pregnancy," and Oscar Costa-Mandry, San Juan, "Extension of Laboratory Service in Puerto Rico." Dr. Carpenter also addressed the San Juan County Medical Society, April 29, on "The Mode of Action of Sulfanilamide and Its Derivatives," and Dr. Kenneth B. Turner, New York, April 19, on "The Chemotherapy of Pneumonia." Dr. Carpenter spent five weeks on the island assisting the department of health in the organization of a program for control of gonorrhea.

GENERAL

Increase in Spotted Fever.—The U. S. Public Health Service reported a sharp rise of Rocky Mountain spotted fever in the Western states during the week ended April 27. Eleven cases were reported in five states, four of them in Montana. The report suggests that health officers issue precautionary measures for the public.

New Medical Director of Riggs Foundation.—Dr. Horace K. Richardson was elected medical director of the Austen Riggs Foundation, Inc., at its annual meeting in Stockbridge, May 11, succeeding Dr. Austen F. Riggs, who died March 5. Dr. Robert B. Hiden was elected senior assistant medical director and Dr. Charles H. Kimberly, junior assistant medical director.

Special Society Elections.—Dr. George E. Bennett, Baltimore, was chosen president-elect of the American Orthopaedic Association at its recent session in Kansas City, and Dr. David E. Robertson, Toronto, was installed as president. Other officers include Drs. Norman T. Kirk, San Francisco, vice president; Charles W. Peabody, Detroit, secretary, and Rexford L. Diveley, Kansas City, Mo., treasurer. Toronto was tentatively selected as the place for the 1941 meeting. — Dr. David Cheever, Boston, was elected president of the American Surgical Association at its recent meeting in St. Louis; other officers include Drs. Howard C. Naffziger, San Francisco, and Roscoe R. Graham, Toronto, vice presidents. The convention in 1941 will be in White Sulphur Springs, W. Va.

Librarians Meet.—The forty-second annual meeting of the Medical Library Association will be held at the Heathman Hotel, Portland, Ore., June 25-27. There will be a symposium on history and literature of epidemiology with emphasis on some Pacific Coast aspects, with Dr. Thomas L. Meado, Harry J. Sears, Ph.D., Portland, discussing plague; William Levin, D.P.H., Portland, tularemia, and Cornelius D. Philip, Ph.D., Hamilton, Mont., Rocky Mountain spotted fever. Olof Larzell, Ph.D., Portland, will direct a panel discussion on methods in regional medical historical research and Dr. Clarence A. Smith, Seattle, will discuss "Growth, Development and Problems of a Regional Medical Periodical." Other

speakers will include Miss Lucy M. Lewis, Oregon State System of Higher Education, "Use of Microfilm in Library Instruction and Service"; Dr. Ira A. Manville, associate clinical professor of nutrition, University of Oregon Medical School, Portland, "Bibliographic Problems Based on a Study of Terminology in the Field of Nutrition," and Miss Amelia Feary, University of Oregon Medical School, "The Medical Social Worker Looks to the Library."

Committees to Cooperate with Army and Navy Medical Corps.—The division of medical sciences of the National Research Council has appointed the following committees to cooperate with the medical corps of the U. S. Army and Navy:

Committee on Chemotherapeutic and Other Agents:

Dr. Perrin H. Long, chairman, Baltimore.
Dr. Frances G. Blake, New Haven.
Dr. John S. Lockwood, Philadelphia.
Dr. John F. Mahoney, Staten Island, N. Y.
Dr. Eli Kennerly Marshall Jr., Baltimore.

Subcommittees:

Infectious Diseases, Dr. Blake, chairman.
Tropical Diseases, Dr. Wilbur A. Sawyer, New York, chairman.
Venereal Diseases, Dr. Joseph E. Moore, Baltimore, chairman.
Wounds and Burns, Dr. Everts A. Graham, St. Louis, chairman.

Committee on Transfusions:

Dr. Walter B. Cannon, Boston, chairman.
Dr. Alfred Blalock, Nashville, Tenn.
Dr. Everett D. Plass, Iowa City.
Dr. Max M. Strumia, Bryn Mawr, Pa.
Dr. Cyrus C. Sturgis, Ann Arbor.

Subcommittees:

Blood Substitutes, Dr. Sturgis, chairman.
Anesthesia in Shock, Dr. Blalock, chairman.

These committees are the result of an informal request for advice from the two medical corps.

Guggenheim Fellowships Awarded.—Among seventy-three fellowships recently awarded by the John Simon Guggenheim Foundation were the following for research on medical and allied topics: Gregory Pincus, Sc.D., Clark University, Worcester, Mass., fellowship renewed for investigation of the developmental physiology of mammalian eggs and embryos; Myron Gordon, Ph.D., research zoologist, New York, genetic studies and investigation of neoplastic diseases in vertebrate animals; Dr. David L. Drabkin, assistant professor of physiological chemistry, University of Pennsylvania School of Medicine, Philadelphia, research on biologic oxidation-reduction processes with William Mansfield Clark, Sc.D., De Lamar professor of physiological chemistry and director of the department of physiological chemistry, Johns Hopkins University School of Medicine, Baltimore; Berry Campbell, Ph.D., assistant professor of anatomy, University of Oklahoma School of Medicine, investigation of the integrative mechanisms of the spinal cord; John Tileston Edsall, associate professor of biological chemistry and tutor in biochemical sciences, Harvard Medical School, Boston, studies of the physical chemistry of amino acids, peptides, proteins and related compounds, and Raymond L. Zwemer, Ph.D., Columbia University College of Physicians and Surgeons, New York, study of factors involved in the maintenance by living cells of a differential permeability to electrolytes, to be carried out at the University of Buenos Aires, Argentina, in association with Dr. Bernardo A. Housay, professor of physiology.

Safety Awards for 1939.—Rhode Island among states and Kansas City among cities won the national grand awards of the National Safety Council for the best safety records and programs of activity during 1939. Rhode Island in addition won first place in the eastern division of states, Minnesota in the midwestern division, Washington in the western division and Oklahoma in the southern division. Cities that won first place in their population groups were Cleveland among cities of 500,000 or more population, Kansas City in the 250,000 to 500,000 population group, Worcester, Mass., in the 100,000 to 250,000 group, Pontiac, Mich., in the 50,000 to 100,000 group, Foxburg, W. Va., in the 25,000 to 50,000 group, and Aberdeen, S. D., in the 10,000 to 25,000 group. In addition there was a special honor roll of 179 cities of from 5,000 to 10,000 population that went through 1939 without a traffic death. At the annual award dinner held at the Drake Hotel in Chicago a special award was given to Edward G. Robinson "because on many occasions he has devoted his popular radio program 'Big Town' to a dramatic and powerful appeal for safer driving and walking." Kansas City won the award "because of its remarkable reduction of 53 per cent in its traffic deaths, the result of an unusually comprehensive program carried on by the city traffic engineer, the police department, the schools and the Kansas City Safety Council," the National Safety Council announced. Rhode Island achieved a rate of only four traffic deaths per hundred million vehicle miles, the lowest rate for any state and less than one third of the national average.

CANADA

Summer School at Vancouver.—The annual summer School of the Vancouver Medical Association will be held, June 25-28, at the Hotel Vancouver in Vancouver. The lecturers will be:

Dr. William S. Middleton, dean and professor of medicine, University of Wisconsin Medical School, Madison.
Dr. Frederick L. Reichert, professor of surgery, Stanford University School of Medicine, San Francisco.
Dr. Philip C. Jeans, professor of pediatrics, State University of Iowa College of Medicine, Iowa City.
Dr. William Wagner, assistant professor of pathology, University of Toronto Faculty of Medicine, Toronto.
Dr. Alfred W. Farmer, junior demonstrator of surgery, University of Toronto Faculty of Medicine, Toronto.

Information may be obtained from Dr. Harold H. Caple, 203 Medical Arts Building, Vancouver, B. C.

Awards in Health Conservation Contest.—First award in the rural health conservation contest sponsored by the Canadian Public Health Association in cooperation with the American Public Health Association and financed by the W. K. Kellogg Foundation went to the St. James-St. Vital full time health unit in Manitoba. The medical officer is Dr. Irving M. Cleghorn, Winnipeg. Awards of merit were given to the Terrebonne County health unit, St. Jerome, Que.; Foothills full time health district, High River, Alberta; Nicolet County health unit, Nicolet, Que., and Laviolette County health unit, Grand' Mère, Que. A special award for having won the Canadian contest twice and for having maintained its high standard in 1939 went to the health unit of the counties of St. Jean, Iberville, Laprairie and Napierville, Que.

FOREIGN

Cameron Prize Awarded to Dr. Dodds.—The University of Edinburgh has awarded the Cameron Prize to Dr. Edward Charles Dodds, professor of biochemistry, University of London, for his work on synthetic estrogens, the *British Medical Journal* reports. Dr. Dodds is director of the Samuel Augustine Courtauld Institute of Biochemistry, chemical pathologist to the Middlesex Hospital and the Royal National Orthopedic Hospital. He is the author of "Recent Advances in Medicine" (with G. E. Beaumont); "The Chemical and Physiological Properties of the Internal Secretions" (with F. Dickens); and "The Laboratory in Surgical Practice" (with L. E. H. Whitby), as well as of various papers in medical periodicals.

Government Services

Dr. McCoy to Retire from Public Health Service

Dr. George Walter McCoy, professor of preventive medicine and public health, Louisiana State University School of Medicine, New Orleans, will retire from the U. S. Public Health Service, June 30, after forty years' active service. Dr. McCoy graduated at the University of Pennsylvania School of Medicine, Philadelphia, in 1898 and served his internship at the City Hospital, Newark, N. J. He entered the U. S. Marine Hospital Service, now the U. S. Public Health Service, in 1900. In 1913 he was made surgeon in the public health service and in 1930 medical director. He was in charge of the plague laboratory in San Francisco, 1908-1911, and director of the leprosy investigation station in Hawaii, 1911-1915, when he also acted as medical and sanitary adviser to the Territorial Government of Hawaii. In 1915 he was detailed as director of the Hygienic Laboratory, now the National Institute of Health, in Washington, D. C., where he served until 1937. Since then he has been engaged in epidemiological studies on leprosy and since 1938 has been director of the department of preventive medicine and public health at the Louisiana State University School of Medicine, New Orleans. From 1922 to 1927 he represented the United States on the Permanent Standards Commission of the Health Section of the League of Nations. He has been a member of the Council on Pharmacy and Chemistry of the American Medical Association since 1915 and of the U. S. Pharmacopeial Revision Committee since 1920. In 1931 he was awarded the Sedgwick Memorial Medal of the American Public Health Association. As a member of the Committee for the Protection of Medical Research of the American Medical Association for about twenty years Dr. McCoy had the responsibility of providing congressional committees with information in connection with bills introduced by antivivisectionists and antivaccinationists which had for their purpose the hampering of scientific progress in medicine through animal experimentation.

May 10, 1940.

Conscription of the Medical Profession

The result of the great expansion of the army is that 90 per cent of the medical officers were civilian physicians until a few months ago. For the regular medical service the limit of the age for admission was fixed at 38 years at the time of the outbreak of war; it has since been raised to 50 years. It is now proposed to conscript the medical profession up to that age.

A Visor for the Prevention of War Injuries of the Eye

At the annual congress of the Ophthalmological Society, Sir Richard Cruise demonstrated a visor which he invented for attachment to the steel helmet worn by soldiers. By a single movement it can be brought down over the upper part of the face and similarly can be retracted within the helmet. The mesh is so fine that exceedingly small missiles are prevented from entering the eye, while at the same time vision is only slightly limited. Cruise has found that fragmentation from explosives is the primary cause of war blindness. In the last war the majority of ocular injuries were due to small metal fragments penetrating the eye. Cruise believes that well over half the cases of blindness in the last war would have been prevented by the visor, which consists of 22 gage duralumin, molded so as to fit the inner curvatures of the steel helmet, to which it is attached by rivets. A spring adjustment enables it to be kept within the helmet.

The congress unanimously passed a resolution that this visor would prevent the majority of cases of blindness caused by gunshot wounds, and repeated its recommendation, made in 1917, during the last war, that some such visor should be adopted. The resolution was sent to the Admiralty, the War Office and the Home Office.

Idiopathic Ulcerative Colitis

At the Royal Society of Medicine, Mr. L. E. C. Norbury opened a discussion on the surgical treatment of idiopathic ulcerative colitis. In spite of the word "ulcerative" it was uncommon to see ulcers except in advanced stages. The rectum was usually involved. Columns of edematous mucous membrane corresponded to the position of the taenia coli. In severe involvement the epithelium seemed to have almost completely disappeared. He pleaded for more extensive use of appendicostomy as a means for colonic irrigation and application of medications. It was important not to open the appendix until some days after operation, so as to avoid infection of the wound. The appendicostomy should not be closed because of the possibility of relapse. For irrigation warm physiologic solution of sodium chloride or hypotonic saline solution might be used, or a mixture of sodium chloride, sodium bicarbonate and sodium baborate. Cecostomy could be done if the appendix was not available. Terminal ileostomy should be reserved for advanced cases or cases in which appendicostomy failed. Colectomy was unnecessary in the early stages and dangerous later.

Mr. W. H. Ogilvie found the evidence that these patients did better under appendicostomy than under medical treatment unconvincing. It did not rest the colon or enable it to be washed out better than from below. Many cases were arrested by medical treatment. Absolute indications for surgical therapy were stricture, polyposis and fistulas. Presumptive indications were severe loss of blood, a year's unsuccessful bed treatment, a fourth relapse and segmental distribution of the disease. Surgical treatment consisted in exclusion, excision and restoration. Exclusion ileostomy was to be recommended, and colectomy followed at the time of choice. The last stage, implantation of

the ileum into the rectum, should be undertaken only when the patient was really well and the rectum was soft and healed. If defecation could not be restored, colectomy was pointless. Thus ileostomy was in most cases the whole treatment. American writers laid stress on the loss of fluids with ileostomy, but Ogilvie had not found dehydration a problem.

Mr. W. B. Gabriel stressed the importance of spasm of the colon in ulcerative colitis. It might occur in nervous persons from emotional disturbance, vitamin deficiency or trauma. He recommended appendicostomy as the best surgical treatment. It allowed instillation of oil into the colon at night and washing out in the morning.

Sir Arthur Hurst said that the attribution of ulcerative colitis to spasm was fallacious. It should be realized that there was such a thing as medical colitis, in many cases presenting normal sigmoidoscopic appearances. He agreed with Ogilvie that appendicostomy was useless; the proper operation was ileostomy. No elaborate lavage was needed; an inch of soft catheter in the rectum would wash out the cecum and colon. Olive oil was useful in the stomach because it inhibited gastric secretion, but in the colon it decomposed and became irritant. The reason for the unsatisfactory loss of fluid with treatment by ileostomy in America was that there was enteritis as well as colitis. Hurst presented his series of eighty-five private patients treated up to 1937. Of these 77 per cent were well, 10 per cent were not, 2 per cent were definitely ill and the mortality was 9 per cent, which was less than half that quoted for cases in which appendicostomy had been done.

BUENOS AIRES

(From Our Regular Correspondent)

May 3, 1940.

Control of Narcotic Drugs

In accordance with a decree promulgated the latter part of last year and effective Jan. 1, 1940, the importation of heroin and its derivatives into Colombia is prohibited. The same restriction applies to the manufacture of heroin. The cultivation of marihuana is likewise prohibited. Licenses issued to physicians for the treatment of addicts are valid only for two months. They are renewable only if the physician can attest that a reduction in the use of the drug has been achieved; otherwise the patient is consigned to a sanatorium.

In Guatemala, according to a report of E. Arroyave L. in the *Boletín sanitario de Guatemala*, the problem of the illicit use of narcotics has almost disappeared since physicians received official permission to write narcotic prescriptions for addicts who voluntarily submitted to the regulations. The drugs used, in the order of preference, are cocaine, morphine and heroin.

In Mexico extensive measures governing the control of narcotics throughout the country have been drafted by the Oficina de Toxicomanías e Higiene Mental. The department of public health has charge of developing the methods of treatment. All persons who habitually use narcotic drugs without therapeutic necessity are designated as addicts. The dispensing of drugs to addicts is regulated in detail. The health department is charged with organizing the dispensaries and hospitals needed. The isolation of addicts is decided either by the managing physician or by the physician connected with the dispensary, on authorization of the department of mental hygiene. The extent to which the regulations adopted in 1931 have been carried out can be discerned from an article by Salazar Viniegra L. in which he states that so far only one hospital necessary for the treatment of drug addicts is in operation. It is situated in Mexico City and forms an annex of the hospital of mental diseases with a maximum of 100 beds. Habitual users of opiates and marihuana taken there for treatment can be given treatment for only a few days at a time. In consequence patients in the course of three years have been treated there as often as from two to ten times. The medical and

social benefits derived from this hospital are therefore insignificant. The problem is not regarded as serious in Mexico. It is assumed that only 6,000 addicts are found in Mexico City and still fewer in the rest of the country. Of course, the illicit traffic in drugs over the border constitutes a problem.

The National Bacteriologic Institute

The bacteriologic institute of the national department of public health situated in Buenos Aires was founded in 1916, with Prof. Rudolf Kraus, an Austrian bacteriologist, its first director. Kraus was succeeded by Prof. Alois Bachmann. Prof. Alfredo Sordelli has been its director since 1924. The institute has a fourfold function: the preparation of biologic products, the diagnosis and epidemiologic investigation of autochthonous transmissible diseases, research and the control of biologic and other products used for medical and hygienic purposes. On the recommendation of the tenth Pan American Health Conference the institute was chosen by the committee on hygiene of the League of Nations as the distribution center for South America of internationally standard preparations (epinephrine, digitalis, endocrine preparations, vitamins and antitoxins).

The biologic products are prepared by a special division of the institute. In 1938 the value of these preparations exceeded 4,800,000 pesos (about \$1,550,000). The expenditures of the institute, amounting to 260,000 pesos (about \$84,000), were higher than the proceeds from the sales. About 90 per cent of the serums, vaccines and endocrine preparations are dispensed gratuitously to public hospitals, welfare institutions, army and navy hospitals and so on; the remainder is sold. A considerable supply of products, sufficient not only for national needs but for emergency aid rendered to neighboring countries, is kept constantly on hand. The research activities of the institute embrace numerous fields such as the pathology of transmissible diseases of animals and man, the investigations of hitherto unknown pathogenic organisms, numerous bacteriologic and immunologic tasks, infectious diseases and improved methods of biologic preparations. New divisions were organized for the investigation of brucellosis, psittacosis, venereal lymphogranuloma and smallpox virus. The diagnostic division is to be enlarged because of the increased demands made on it by the new law requiring premarital examinations for venereal disease (THE JOURNAL, April 20, p. 1570).

Hospital Service in Buenos Aires

According to a municipal report of Buenos Aires for 1938, about 137,000 patients were received in the federal, municipal and private hospitals, 1.6 per cent more than in 1937. In the polyclinics 3,600,000 cases were handled. Cases requiring surgical intervention amounted to 99,000; 4,200,000 prescriptions were written and 600,000 laboratory tests made. The hospitals for mental diseases received 3,415 persons, lost 619 by death and restored 238 to health. The institute of radiology and physical therapy treated 173,000 patients. There were 25,000 obstetric cases; more than 20,000 children were given attention in the infant welfare stations. Five thousand liters of mother's milk was secured from fifty-four mothers, 3,000 of which was distributed without charge. More than 58,000 children received food assistance; 212,000 persons sought medical advice for tuberculosis and more than a million for venereal diseases. In the Jenner Institute some 385,000 vaccinations were performed; in the Pasteur Institute 37,000 cases of rabies were examined with 25,000 inoculations. Rabies was discovered in 134 animals.

School of Hygiene and Preventive Medicine

The name of the School of Hygiene, founded in 1938 by the university in Santiago de Chile, has been changed to School of Hygiene and Preventive Medicine. It furnishes a theoretical and practical training to workers and assistants in the field of sanitation, directs the organization and control of the schools for social service and nursing, conducts instruction

in hygiene for school teachers and students of the Institute of Pedagogy, promotes the education of the population in social and preventive measures and handles the organization and maintenance of a museum of hygiene. The positions of the head and the teaching staff of the school are appointive positions within the power of the president of the republic. The school awards diplomas in hygiene, social welfare work and nursing.

Congress of Medical Students

The first South American Congress of medical students will be held in the first half of August in Lima, Peru. It is intended to bring the medical students of the different South American countries more closely together.

Malaria Control in Brazil

The Rockefeller Foundation has made this year a grant of \$230,000 for malaria control in Brazil, exceeding its grant of \$100,000 for 1939. According to Dr. Raymond B. Fosdick, its president, the purpose is to confine the disease during the rainy season to areas already infected as the first step to its eradication. The grant of 1939 was made to combat *Anopheles gambiae*, which was introduced into Brazil a few years ago. However, the fact that control measures had been organized at a time when the rainy season had set in prevented the effective execution of the plans. In consequence a malaria epidemic broke out in which 4,000 persons had to be treated. Progress could be reported in combating the mosquitoes in the infested areas of the valleys adjoining the main rivers and in several coastal regions.

Personals

The Guggenheim Foundation has awarded a fellowship to Prof. R. L. Zwemer, of Columbia University, New York. He will conduct research studies in permeability in Buenos Aires with the physiologist Prof. B. Z. Houssay.

Dr. Carlos Valenzuela, of the University La Paz, Bolivia, has received a government fellowship for the study of carcinomas with Prof. Roffo in Buenos Aires. Valenzuela is a radiologist and will study the x-ray diagnosis and therapy of tumors.

PALESTINE

(From a Special Correspondent)

JERUSALEM, April 10, 1940.

Hormone Research Laboratory

After his return from America, Prof. Bernhard Zondek opened the Hormone Research Laboratory at the Medical School (Nathan Ratnoff Building) of the Hebrew University, Jerusalem. Investigations of antihormones and the bleeding mechanism are reported. Observations on *Microtus guentheri*, which belongs to the murides (a family of myomorph rodents of mouselike form), a generally feared crop destroyer, showed that, unlike white mice and rats, it does not have a vaginal cycle involving cornification of the epithelium. Only after 5,000 international units of estrogen does cornification appear. The exceptional character of this animal lies in its behavior to gonadotropic substances of varied origin. Gonadotropic substances in the urine of pregnant women have no reactions. With mare serum a maturation of follicle occurs without luteinization (even with 1,000 units), with animal hypophysis both maturation of follicles and formation of corpus luteum (at 8 rat units) take place. As the *Microtus* family is widespread and is easily bred in laboratories, these murines are of particular importance as test objects in the standardization of gonadotropic substances of varied origin and composition.

Hebrew University in Jerusalem

The head of the ophthalmologic departments of the Hadassah and the chairman of the ophthalmologic department of the University Hospital, Dr. Aryeh Feigenbaum, has been appointed professor at the Hebrew University. Professor Feigenbaum is the editor of *Acta ophthalmologica orientalia*

and collaborator with the *Revista cubana de oto-neuro-oftalmiatria*, Habana, and of the international *Ophthalmologia*, Basle. In 1915 he published the first textbook on ophthalmology in the Hebrew language, and in Didley and Sorsby's "Modern Trends of Ophthalmology," 1940, he has edited the chapter on ophthalmic conditions in tropical and subtropical regions. Professor Feigenbaum is the present dean of the Medical Faculty of the Hebrew University.

The Hadassah University Hospital

The physiologic-chemical department of the Hadassah Hospital and the clinical laboratories have been moved into the Medical School (Ratnoff Building). The department is headed by Prof. E. Wertheimer and is engaged in work on the importance of fat tissues in the metabolism of fat and carbohydrates. To date investigations have shown that the refilling of fat stocks in starving rats is regularly associated with the enrichment of glycogen. Animals without adrenals show no deposition of glycogen and also no addition of fat.

Lina and Nathan Strauss Health Center

At the end of 1939 Prof. W. Strauss, formerly at the Hygienic Institute of the University of Berlin, took over the management of the Health Center, which dedicates its work principally to practical hygiene. Efforts are being made to unite all similar institutes under one direction and special attention is given to the question of adaptation of European immigrants to the conditions of life, work and climate in Palestine. Investigations are proceeding as to the use of orange peels and pulp for food (bread) and a more intensive employment of nuts in order to improve the protein intake in the food of the poorer classes of the population.

New Hospitals

At Haifa the new plan for the construction of the Rothschild-Hadassah Hospital, which is to be situated midway between the Hadar Hacarmel and Mount Carmel, has been authorized. For this construction the plans of Mr. Neufeld, of Tel Aviv, have been accepted. The new building will be fitted with the most modern appurtenances and is to be built at a cost of approximately £P.40,000. At the Tel-Aviv Hadassah Hospital a new wing providing for seventy beds in the children's department has been opened and was put in charge of Prof. L. F. Mayer.

ITALY

(From Our Regular Correspondent)

May 15, 1940.

Karyoklastic Poisons

Professor Dustin, of the University of Brussels, lectured before the Istituto della Sanita pubblica of Rome, in which he said that the main property of karyoklastic poisons of the tryptoflavine group is arresting karyokinesis, which is stimulated by poisons of the arsenic-colchicum group. The speaker gives the name statmokinesis to arrested mitosis with special aspects. These types of mitosis develop in karyokinetic or prekaryokinetic zones. Arsenic and especially colchicum stimulate mitosis. Botanists found that colchicum is of great value in creating new species of useful and ornamental plants.

Lipoids of the Blood

Professor Bertola recently reported the results of experiments on the lipoids of the blood to the Società Medico-Chirurgica di Pavia. Alterations of a nephrosic type were produced in rabbits by means of a diet which was rich in proteins and fats, after which the total and fractional cholesterol and lipids of the blood increased. The amount of fats in the blood of dogs increases slightly after daily administration of small doses of allyl formiate for a short time. If the treatment is administered for a long period of time the increase of fats in the blood is acute and the kidney and liver show functional

and microscopic changes. In clinical cases of hypertrophic chronic hepatitis and acute diffuse hepatitis, the amount of total and fractional lipids in the blood is increased, the lipids in the liver and sometimes those of the kidney are increased, and those in the spleen and heart do not change.

Leukemia and Banti's Disease

Professor Bossa lectured at the Accademia della Scienze mediche e chirurgiche in Naples, with a report of the results of studies on leukemia and Banti's disease. The point of coagulation for normal blood serum varies from 150.8 to 168.8 F. It reaches higher figures in leukemia. A coagulation temperature higher than normal indicates that the amount of globulins and total proteins in the blood is diminished, whereas a point of coagulation at low temperature indicates increase of globulins and total proteins in the blood. The imbalance of the metabolism of proteins in the blood serum of leukemic patients is caused partly by alteration of the water-protein ratio in the blood and by variations in the amount of blood globulins and partly by the nucleoprotein in the blood. The latter precipitates to semisaturation with ammonium sulfate, as though it were a globulin, and coagulates at a temperature higher than that for globulins. Professor Bossa also made spectroscopic studies of the hemoglobin of normal persons and of patients with leukemia. He followed the behavior of the curves of absorption in the spectral photographs. Soret's band of 4,200 angstroms, which is within the limit of visibility and corresponds to hematin, as well as the two main ultraviolet bands corresponding to globin, show slight spectrographic oscillations in normal hemoglobin and wide oscillations in the hemoglobin of patients with leukemia. In the latter the intensity of the bands is attenuated. Because the globulins in hemoglobin of normal adults are of at least two different types (Haurowitz) the speaker believes that anemia in leukemia is due to an imbalance of the globulins and that the spectrographic variations in hemoglobin show the imbalance. Hemoglobin in pernicious anemia does not show spectrographic differences in relation to normal hemoglobin.

Professor Castronuovo, in a lecture before the society, discussed a sign in the spleen in bantian syndromes, which he reported first in 1927. It consists in the presence of hard, elastic and plastic splenomegaly shown by the mark of the finger in the spleen when pressed. It is the sign of Banti's disease and bantian syndromes. It may rarely be induced in some circulatory diseases with hepatosplenic stasis with involvement of the portal circulation. He concluded that (1) splenomegaly in bantian syndromes is hard, elastic and plastic and preserves the marks of finger pressure; (2) the sign of finger mark preservation appears early in the evolution of bantian syndromes and lasts for the first and second stages of the disease, during the precirrhotic condition of the liver. The sign is of diagnostic, prognostic and therapeutic value. In association with the symptoms of the disease it shows indications of splenectomy before establishment of anemia and before development of hepatosplenic sclerosis.

Marriages

BELFORD CHRISTY BLAINE to Miss Mildred Josephine McKnight, both of Pottsville, Pa., June 26.

EDWARD G. SIEGFRIED, Harbor Beach, Mich., to Miss Lois Larson of Waseca, Minn., in May.

BENJAMIN M. KAGAN, Washington, Pa., to Miss Katherine Hamburger of Baltimore, June 2.

DOUGLAS F. HEUER JR. to Miss Raychelle Price, both of Sweetwater, Tenn., recently.

RICHARD G. HODGES, New York, to Miss Barbara Garland of Concord, N. H., June 1.

MILES GRIFFIN, Oakland, Calif., to Miss Jane Volkmann of Piedmont, June 1.

Deaths

David Riesman ☉ Philadelphia, distinguished physician, medical educator and medical historian, died in the University of Pennsylvania Hospital, June 3, aged 73, following a sudden illness.

Dr. Riesman was born in Germany, March 25, 1867, and was brought to the United States when he was a boy, receiving his preliminary education in the public schools of Portsmouth, Ohio. He received his degree of doctor of medicine from the University of Pennsylvania in 1892 and was later awarded the honorary doctor of science by the same university. He also received the honorary degree of doctor of laws from the University of Wisconsin in 1937.

After graduation he taught pathology and practiced clinical medicine for eight years. In 1900 he became professor of clinical medicine in the Philadelphia Polyclinic. In 1908 he became associated with the University of Pennsylvania School of Medicine and rose to the position of professor of clinical medicine, holding that position from 1912 to 1933, when he became emeritus professor. Since 1933 he had also been professor of history of medicine and professor of clinical medicine in the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania. During the World War he entered the Army Medical Corps with the rank of first lieutenant and retired as lieutenant colonel.

In organizational work Dr. Riesman was exceedingly active. He was a fellow of the American College of Physicians, of the College of Physicians of Philadelphia and of the American Association for the Advancement of Science. He had been president of the Philadelphia County Medical Society, of the Philadelphia Pathological Society, of the American Society of Medical History and of the Inter-State Post-graduate Medical Association of North America. He was also a member of the Association of American Physicians and of the American Gastro-Enterological Association. In general science, he was a member of the Franklin Institute, the Society for the History of Science, the Academy of Natural Sciences and the British Philosophical Association. He had received the Order of the Cavaliere of the Crown of Italy, returning this order to show his opposition to fascism.

Dr. Riesman was a prolific contributor to writings in the fields of pathology, medicine and medical history. With Dr. Ludwig Hektoen, he was editor of the "American Textbook of Pathology" in 1901. He wrote a "Life of Thomas Sydenham" and a work called "Medicine in the Middle Ages"; his essays were collected in book form, and he was a contributor to numerous systems and textbooks in the practice of medicine.

Among his hobbies were astronomy, archeology, atomic physics and the writings of Shakespeare.

Dr. Riesman was the first recipient of the Strittmatter award, given annually by the Philadelphia County Medical Society for the greatest service to medicine in that city.

In all his attitudes he was distinctly a liberal, tending toward profound sympathy for all liberal causes and lending his influence to their promotion.

In his death, in addition to his widow, he leaves two sons, David Jr., who is professor of law at the University of Buffalo, and John P., now an intern at the Philadelphia General Hospital, and a daughter Mary, who is a teacher in New York.

In conferring on him the degree of doctor of laws, President Dykstra of the University of Wisconsin referred to him as "a statesman in the field of medicine." In 1933 at the time of his retirement as professor of clinical medicine, the graduating class of the University of Pennsylvania presented him with a plaque on which were inscribed the words "Learned Scholar, Inspiring Teacher, Great Physician."

DAVID RIESMAN, M.D.
1867-1940

Worcester Allen Bryan ☉ Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1899; assistant in medicine, 1899-1900, assistant surgeon and demonstrator of surgery from 1900 to 1907, lecturer of principles of surgery from 1902 to 1906, adjunct professor of surgery from 1906 to 1909, professor of principles of surgery from 1909 to 1911, professor of surgery and clinical surgery from 1911 to 1925 and since 1925 professor of clinical surgery at his alma mater; professor of oral surgery in the dental department of Vanderbilt University from 1902 to 1925; member of the Southern Surgical Association; fellow of the American College of Surgeons; surgeon to the Nashville General Hospital, Protestant Hospital and the Vanderbilt Hospital, Nashville, and the Watauga Sanitarium, Ridgetop; author of "Principles of Surgery"; aged 66; died, April 30, in Memphis of coronary occlusion.

Henry Johns Berkley, Baltimore; University of Maryland School of Medicine, Baltimore, 1881; member of the Medical and Chirurgical Faculty of Maryland and the American Psychiatric Association; clinical professor emeritus of psychiatry at Johns Hopkins University School of Medicine; formerly member of the board of mental hygiene of Maryland; author of "Text Book of Mental Diseases"; aged 79; died, April 5, in the Maryland General Hospital of injuries received in a fall.

Arthur Camp Stanley ☉ Washington, D. C.; George Washington University School of Medicine, Washington, 1906; entered the navy in 1908 and retired in 1910 for incapacity resulting from an incident of service, with rank of lieutenant commander; served during the World War; fellow of the American College of Surgeons; on the staff of the Garfield Memorial Hospital; aged 56; died, April 30, of hypertension, uremia and arteriosclerosis.

William A. Deerhake ☉ Waupun, Wis.; Indiana University School of Medicine, Indianapolis, 1908; acting assistant surgeon, United States Public Health Service, 1909-1910; served during the World War; connected with the Veterans Bureau from 1921 to 1926; since 1926 medical superintendent of the Central State Hospital for Insane; aged 54; died, April 10, of injuries received in an automobile accident.

Carroll Royer Baker ☉ Medical Director, Captain, U. S. Navy, Washington, D. C.; Jefferson Medical College of Philadelphia, 1909; entered the navy May 20, 1914; fellow of the American College of Surgeons and the American College of Physicians; aged 55; on the staff of the United States Naval Hospital, where he died, April 23, of cerebral thrombosis and arteriosclerosis.

John Hill Tucker ☉ Charlotte, N. C.; University of Virginia Department of Medicine, Charlottesville, 1899; fellow of the American College of Surgeons; past president of the Mecklenburg County Medical Society; on the staffs of Mercy Hospital and St. Peter's Hospital; aged 62; died, April 21, of carcinoma of the superior mediastinum.

Platt Walker Covington ☉ Salt Lake City; University of Maryland School of Medicine, Baltimore, 1908; member of the Medical Society of the State of North Carolina; western director of the International Health Division of the Rockefeller Foundation; aged 55; died, April 20, in a hospital at Baltimore of cerebral hemorrhage.

John Edward Hardman ☉ Youngstown, Ohio; College of Physicians and Surgeons, Baltimore, 1909; past president of the Mahoning County Medical Society; past president of the staff of St. Elizabeth's Hospital; aged 54; died, April 4, in the Cedars of Lebanon Hospital, Los Angeles, of nephritis and hypertension.

Henry Mateland Mills ☉ Brooklyn; Long Island College Hospital, Brooklyn, 1898; at one time clinical professor of obstetrics and gynecology at his alma mater; fellow of the American College of Surgeons; on the staff of the Kings County Hospital; aged 70; died, April 26, of myocarditis.

Michael J. Foran, Ithaca, N. Y.; Baltimore Medical College, 1902; University of Buffalo School of Medicine, 1904; member of the Medical Society of the State of New York; formerly county coroner; aged 67; died, April 5, at the Johns Hopkins Hospital, Baltimore, of myocarditis.

James Reed Davis, McKees Rocks, Pa.; University of Pittsburgh School of Medicine, 1911; member of the Medical Society of the State of Pennsylvania; on the staff of the Ohio Valley Hospital; aged 54; died, April 10, in the Mercy Hospital, Pittsburgh, of carcinoma of the bladder.

Roy Dean Russell ☉ Dodge City, Kan.; University of Pennsylvania School of Medicine, Philadelphia, 1922; fellow of the American College of Surgeons; on the staff of St. Anthony Hospital; aged 43; died, March 19, of acute endocarditis following a streptococcal infection of the leg.

Adam L. Kotz ☉ Easton, Pa.; Jefferson Medical College of Philadelphia, 1881; member of the American Society of Clinical Pathologists; emeritus chief of the laboratory of the Easton Hospital; on the staff of the Sacred Heart Hospital from 1922 to 1926; aged 84; died, March 17.

James Joseph Hagan Jr., Jersey City, N. J.; Georgetown University School of Medicine, Washington, D. C., 1936; on the staffs of the Medical Center of Jersey City and St. Francis Hospital; aged 31; died, April 2, of cardiac thrombosis and streptococcal infection of the throat.

Frederick Whitmore Harriman ☉ Montpelier, Vt.; University of Vermont College of Medicine, Burlington, 1911; fellow of the American College of Surgeons; served during the World War; on the staff of the Heaton Hospital; aged 51; died, April 22, of coronary sclerosis.

William Daniel Kelly, St. Paul; Jefferson Medical College of Philadelphia, 1887; member of the American Urological Association; aged 75; formerly on the staff of St. Joseph's Hospital, where he died, April 7, of coronary thrombosis and essential hypertension.

Ferdinand Seidl ☉ Benson, Ill.; St. Louis College of Physicians and Surgeons, 1894; formerly county coroner, mayor and member of the school board; aged 81; died, April 30, in St. Francis Hospital, Peoria, of pyelonephritis and hypertrophy of the prostate.

Arthur Davis Variell, Kennebunk Maine; Medical School of Maine, Portland, 1894; past president of the board of health of Waterbury, Conn.; aged 71; died, April 16, in Miami Beach, Fla., of cerebral embolus and hypertensive heart disease.

Philip Schuyler Doane ☉ Pasadena, Calif.; Rush Medical College, Chicago, 1895; fellow of the American College of Surgeons; aged 67; died, April 27, in the Collis P. and Howard Huntington Memorial Hospital of coronary thrombosis.

John Robert Brownell ☉ Perry, N. Y.; Chicago Homeopathic Medical College, 1899; served during the World War; health officer; aged 63; died, April 10, in the Wyoming County Community Hospital, Warsaw, of carcinoma of the cecum.

Herman Jeremiah Ballen, New York; New York Homeopathic Medical College and Flower Hospital, New York, 1916; served during the World War; aged 44; died, April 25, in a hospital at New Haven, Conn., of tuberculosis.

Milton Earl Wilson ☉ Coquille, Ore.; University of Oregon Medical School, Portland, 1924; part owner of the Coquille Hospital; aged 43; died, April 27, in a hospital at Portland of subacute bacterial endocarditis.

William Francis Hayes, Beverly, Mass.; Tufts College Medical School, Boston, 1909; member of the Massachusetts Medical Society; aged 57; died, April 4, in the Beverly Hospital of asthma, bronchitis and emphysema.

Franklin Pierce Vines, El Dorado, Ark.; Memphis (Tenn.) Hospital Medical College, 1903; member of the Arkansas Medical Society; on the staff of the Warner Brown Hospital; aged 62; died, April 29, of cerebral hemorrhage.

William Harmar Good ☉ Philadelphia; Medico-Chirurgical College of Philadelphia, 1897; formerly demonstrator and instructor of physiology at his alma mater; aged 63; died, April 21, of a self-inflicted bullet wound.

William Henry Jenks, Pasadena, Calif.; Chicago College of Medicine and Surgery, 1913; member of the Iowa State Medical Society; served during the World War; aged 54; died, April 22, of cerebral hemorrhage.

Martin Flaherty Bancroft, San Diego, Calif.; Stanford University School of Medicine, San Francisco, 1933; member of the California Medical Association; aged 33; died, April 12, of a gunshot wound of the chest.

Byron Bowman Bobb ☉ Harrisburg, Pa.; Temple University School of Medicine, Philadelphia, 1926; aged 41; formerly on the staff of the Harrisburg Polyclinic, where he died, April 7, of intestinal obstruction.

Herbert Augustus Allen, Richmond, Va.; Howard University College of Medicine, Washington, D. C., 1912; on the staff of the Richmond Community Hospital; aged 55; died, April 30, of cerebral hemorrhage.

Francis Bernard Hunter, San Diego, Calif.; The School of Medicine of the Division of Biological Sciences of the University of Chicago, 1936; aged 28; died, April 24, in Mercy Hospital of acute leukemia.

William Oakes Hewitt ☉ Attleboro, Mass.; Harvard Medical School, Boston, 1900; formerly city health officer; aged 62; died, April 27, in the Phillips House of the Massachusetts General Hospital, Boston.

Smith Fuller Hogsett ☉ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1906; on the staffs of St. John Hospital and the Passavant Hospital; aged 57; died, April 5, of coronary occlusion.

Richard Edwin Stoner, Cincinnati; Western Reserve University School of Medicine, Cleveland, 1937; aged 28; resident to the Cincinnati General Hospital, where he died, April 20, of cerebral hemorrhage.

Edward Marion Gramm, Philadelphia; Hahnemann Medical College of Philadelphia, 1880; formerly professor of dermatology at his alma mater; aged 80; died, April 1, of cerebral hemorrhage.

Donnell Bone Braly, Troup, Texas; University of Nashville (Tenn.) Medical Department, 1907; member of the State Medical Association of Texas; aged 63; died, April 21, of myocarditis.

Henry Costello Foster, Clear Spring, Md.; University of Maryland School of Medicine, Baltimore, 1889; aged 72; died, April 29, in the University Hospital, Baltimore, of coronary thrombosis.

Glenn Guy Towsley, Grand Rapids, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1894; aged 73; died, April 23, of coronary sclerosis and cerebral arteriosclerosis.

Frank S. Twitty, Columbia, Ala.; College of Physicians and Surgeons, Baltimore, 1893; aged 70; died, April 30, in a hospital at Dothan of cerebral hemorrhage and arteriosclerosis.

Philip Nicholson Wharton, Munising, Mich.; Northwestern University Medical School, Chicago, 1927; aged 38; died, April 21, of hemorrhage due to a severed artery of the thumb.

Osstella Fitch Blakely, Fairfield, Ill.; Barnes Medical College, St. Louis, 1908; aged 56; died, April 22, in the Good Samaritan Hospital, Vincennes, Ind., of chronic myocarditis.

Norman Baker Ervin, Gibsonburg, Ohio; University of Wooster Medical Department, Cleveland, 1881; aged 87; died, April 29, of arteriosclerosis and coronary occlusion.

David Arthur Mills ☉ Zephyrhills, Fla.; University of Michigan Homeopathic Medical School, Ann Arbor, 1912; aged 61; died, April 23, of cerebral hemorrhage.

Charles H. Erdman, Stanley, Wis.; University of Tennessee Medical Department, Nashville, 1893; aged 68; died, April 25, in the Victory Hospital of cerebral hemorrhage.

Reginald Heber Cleary, Caldwell, Ohio; Starling Medical College, Columbus, 1902; served during the World War; aged 65; died, April 27, of coronary heart disease.

Mary L. Van Meter Kelly, Inglewood, Calif.; Woman's Medical College of Pennsylvania, Philadelphia, 1884; aged 88; died, March 14, of chronic myocarditis.

Henry George Rose, Denver; Gross Medical College, Denver, 1896; served during the World War; aged 75; died, April 15, of rheumatic heart disease.

Edmund Johnson Jr., Anderson, S. C.; Leonard Medical School, Raleigh, 1910; aged 58; died, April 21, in the Anderson County Hospital of diabetes mellitus.

Rudolph Mueller, Evanston, Ill.; C. K. Ceská Universita Karlo-Ferdinandova, Prague, Bohemia, Austria, 1909; aged 54; died, March 21, of carcinoma.

Arthur E. Shappell, Van Nuys, Calif.; Keokuk (Iowa) Medical College, 1895; served during the World War; aged 71; died, March 7, of arteriosclerosis.

Solomon Hyman ☉ Los Altos, Calif.; Johns Hopkins University School of Medicine, Baltimore, 1902; aged 65; died, March 13, of coronary occlusion.

Emile R. Paillou, St. Louis; Hahnemann Medical College and Hospital of Philadelphia, 1893; aged 75; died, April 26, of hypostatic pneumonia.

Ulvus L. Russell, Los Angeles; Washington University School of Medicine, St. Louis, 1893; aged 68; died, March 13, of myocarditis.

Joseph Richard Sample, Haines City, Fla.; Lincoln (Neb.) Medical College of Cotner University, 1897; aged 73; died, March 14.

J. A. Hamilton, Decatur, Ohio; College of Physicians and Surgeons, Baltimore, 1883; aged 80; died, March 22, of heart disease.

James L. W. Young, Portland, Ore.; Missouri Medical College, St. Louis, 1871; aged 91; died, April 29, of myocarditis.

Charles Augustus Arnold ☉ Pittsburgh; Baltimore Medical College, 1902; aged 70; died, April 6, of coronary occlusion.

Correspondence

DIAGNOSIS OF ALCOHOLIC INTOXICATION

To the Editor:—The observations of Swimm, McCawley and Leake (Correspondence, *THE JOURNAL*, March 23, p. 1098) who noted appreciably high concentrations of alcohol (up to 0.15 per cent) in the blood of normal rabbits, using Heise's method, are rather surprising.

In approximately 1,600 determinations of alcohol in blood and urine (Studies in Alcohol: I. Diagnosis of Acute Alcoholic Intoxication by a Correlation of Clinical and Chemical Findings, *Am. J. M. Sc.* 196:475-487 [Oct.] 1938) of persons suspected of acute alcoholism, I noted negative results in about 400 cases using Heise's method. No substances have been found, in my experience, which yield a detectable reducing action in the blood or urine of the normal human being. The urine of approximately 200 nonalcoholic subjects was tested and gave negative results for alcohol. Blood taken from persons in full ether anesthesia also gave negative results. Furthermore, in a series of twenty volunteers to whom alcohol was administered, the fasting blood was negative for alcohol in all instances (Studies in Alcohol: II. Experimental Feeding of Alcohol to Non-alcoholic Individuals, *ibid.*, p. 487). Formaldehyde interferes but may be easily detected and removed. Patients in severe acidosis have shown positive results for alcohol in both blood and urine, but the results have never exceeded 0.03 per cent. These figures are insignificant for medicolegal interpretation.

Using Harger's method for the determination of alcohol in tissues, a more sensitive procedure, I have had results varying from 0.0009 to 0.0039 per cent of alcohol in the blood on 125 nonalcoholic persons (Studies in Alcohol: III. Relation of Alcohol Absorption to Gastric Acidity, to be published). This so-called normal blood alcohol content compares similarly with the results of other observers. In some preliminary work, it has been noted that the normal dog approximates these figures.

All these results are so low that they cannot possibly interfere with the legal interpretation of the test for alcohol. It is concluded, therefore, that either Heise's or Harger's method is entirely satisfactory for medicolegal purposes.

WALTER W. JETTER, M.D., Taunton, Mass.

WHY "REFRIGERATION"?

To the Editor:—Medical nomenclature should be simple, expressive and consistent. The current interest in lowering body temperature for therapeutic purposes by suitable cooling arrangements has resulted in newspaper headlines such as "Artificial Hibernation," "Frozen Sleep" and "Refrigeration." It is regrettable to find the repetition of such sensational titles in medical papers and in medical publications of standing. Artificial fever therapy has become generally designated under the term "hyperthermy" or "hyperpyrexia" and no one would think of speaking of the procedure as body "cooking" or "roasting" because external or internal forms of heating are applied. Hence it would appear logical for describing the reverse process of lowering the body temperature to employ the term "hypothermy." This would also tend to convey a sound conception of the physiologic process involved, which amounts only to a moderate lowering of the body temperature and can be accomplished by air cooling as well as by packing with ice.

Body cooling by applications of cold water has formed one of the standard methods of hydrotherapy for many years, while the term cryotherapy or cryotherapy has been employed principally to describe local cooling or actual tissue destruction such as by freezing with a carbon dioxide pencil or paste. The analogy of medical and surgical diathermy offers the term

surgical hypothermy or cryotherapy for describing the use of cold for local tissue destruction, while medical hypothermy could designate the use of a cold compress or an ice bag over a circumscribed body area. Hence, in summary, the term general hypothermy would appear logical to denote the lowering of body temperature by any form of general cooling, while local hypothermy, medical or surgical, would seem appropriate to denote local cooling or freezing, respectively.

RICHARD KOVACS, M.D., New York.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CARDIAC IRREGULARITY

To the Editor:—A high school student aged 17 consulted me recently because of shortness of breath and dizziness during athletic exertion. This boy has been active in athletics in the last few years and is still rapidly growing. At present he weighs 170 pounds (77 Kg.) and measures 6 feet 5 inches (196 cm.) in height. His symptoms have certainly not been of more than one month's duration. On examination I found an absolute irregularity of the heart rhythm with a tachycardia and pulse deficit. His blood pressure was approximately 148 systolic, 100 diastolic. No other evidence of organic heart disease, such as an enlargement of the heart, murmurs or evidence of decompensation could be found. My impression is that he has an auricular fibrillation of the idiopathic type. Could his strenuous athletic activities be responsible for this? I advised bed rest and sedation in the hope that the normal rhythm would spontaneously reestablish itself. However, the boy did not cooperate well with regard to the rest regimen and after two weeks without success with home treatment I decided to hospitalize him and employ more specific therapy. For the past ten days he has been receiving quinidine sulfate 5 grains (0.3 Gm.) and strychnine one-thirtieth grain (0.002 Gm.) three times a day. As yet a persistent normal rhythm has not returned, but the pulse is quieter and apparently regular for short intervals. An electrocardiogram has not been made, since we do not have the facilities here. How long should I continue with the quinidine and strychnine? Any additional suggestions for therapy would be appreciated.

J. M. Spatz, M.D., Glasgow, Mont.

ANSWER.—From the data given one cannot definitely identify the arrhythmia. Auricular fibrillation is by far the commonest mechanism which produces this type of irregularity, but multiple premature beats and auricular flutter with varying conduction can show a similar irregular rhythm. The fact that the pulse later became apparently regular for short intervals tends to cast some doubt on the diagnosis of auricular fibrillation. In such a case an electrocardiogram would be invaluable in identifying the arrhythmia.

Auricular fibrillation has been reported to occur not infrequently in otherwise normal hearts, and heavy exertion is implicated as the exciting cause in some of these cases. It would be well, however, to search carefully for evidence of organic disease. This arrhythmia is well known to complicate rheumatic heart disease frequently, but it must be remembered that it also occurs commonly in thyrotoxicosis. Occasionally the occurrence of auricular fibrillation directs attention to the latter possibility and results in the discovery of a "latent" hyperthyroidism. The fact that the arrhythmia has persisted for twenty-four days suggests an organic etiology but is not definite proof, because "idiopathic" fibrillation rarely may persist for a long time. The cause of a blood pressure reading of 148/100 should also be investigated. At this age a chronic glomerulonephritis or a coarctation of the aorta should be especially considered. Auricular fibrillation per se does not elevate the blood pressure, although it does make measurement difficult.

Treatment may well be first directed at an attempt to convert the auricular fibrillation, if this is present, to sinus rhythm, and for this quinidine in the form of the sulfate is the drug of choice. Different regimens have been recommended, and the following is one which has proved satisfactory: Quinidine sulfate tablets 0.2 Gm. (3 grains) by mouth are employed throughout. One tablet is given the first day to test for sensitivity. On the second day one tablet is given every four hours for five doses (sometimes administration every four hours day and night is advised; however, it is usually preferable to omit the sixth dose and thus allow eight

hours of uninterrupted sleep). Each day thereafter one tablet is added to the daily total, so that six tablets are given on the third day, seven on the fourth day, and so on, until the seventh day, when ten tablets (2 Gm.) are given. This procedure is stopped when the rhythm is converted or at the end of the seventh day if the arrhythmia persists. If sinus rhythm returns, it is well to give three tablets of quinidine a day for the first few weeks, at least, to prevent recurrence. If the auricular fibrillation persists, however, a second course similar to the first may be given after a rest period of from two to three weeks, and even a third course after a like period. If the fibrillation persists after three courses, further attempts are probably of no avail. Full digitalization before, with continuance of maintenance dosage during, quinidine therapy is commonly employed. Besides being of definite value in maintaining a slow, and therefore more efficient, ventricular rate the digitalis may potentiate the action of quinidine in breaking the mechanism of auricular fibrillation. The use of strychnine in conjunction with quinidine has been recommended empirically. If the fibrillation cannot be converted to sinus rhythm, a continuous maintenance administration of digitalis is advisable to control the ventricular rate if it is rapid.

MOOTS-MCKESSON RATIO AND OPERATIVE RISK

To the Editor:—In Malingot's *Post Graduate Surgery* I find a reference to the "Moots-McKesson pressure ratio" as an index of circulatory efficiency. In the section dealing with carcinoma of the colon and rectum the statement is made that a Moots-McKesson ratio of 25 indicates that surgery will be fatal. An index of 50 is given as the optimal, while 75 or over indicates an increased risk. No details are given as to the method of determining this ratio and I do not find any references to it in any of my literature. An explanation and references to literature would be appreciated.

Thomas C. McVeagh, M.C., Honolulu, Hawaii.

ANSWER.—In 1916 Dr. Charles W. Moots presented at the annual meeting of the American Association of Obstetricians and Gynecologists a paper entitled "Observations on Blood Pressure During Operations." This was the result of work in which Dr. E. I. McKesson helped him. Moots and McKesson had formulated as a result of some years of experience in anesthesia and surgery a blood pressure ratio or index for operability. This consisted of a fraction, namely the pulse pressure divided by the diastolic pressure. Moots claimed that the relatively normal value for safety in operations lies between 25 and 75 per cent. Thus, a case in which the pulse pressure is 40 and the diastolic pressure is 80, giving a 50 per cent ratio, would be just about ideal. The pulse pressure of course is the difference between the systolic and the diastolic pressure.

Ten years later Moots wrote further on the evaluation of surgical risk, blood pressure protection and nitrous oxide-oxygen anesthesia, reemphasizing the value of his pressure ratio or index for operability (Evaluation of Risk, Blood Pressure Protection, and Nitrous Oxide-Oxygen Anesthesia as Vital Factors in Safer Gastric Surgery, *Brit. M. J.* 2:295 [Aug. 14] 1926; *Anesth. & Analg.* 5:298 [Dec.] 1926).

However, W. S. Sykes (Evaluation of Operative Risk: Criticism, *Anesth. & Analg.* 13:99 [May-June] 1934) published a criticism of Moots's method of evaluation of operative risk. Sykes cited several cases in which the formulas were normal but death occurred. He concluded, therefore, that there was no reliance to be placed in the formulas taken by themselves and that fifteen of twenty-four results that he studied himself were unreliable. The patients were seriously ill, however, and in general he conceded that the formula might have some value if the condition of the patient otherwise was taken into consideration.

MIGRAINE AND HISTAMINE

To the Editor:—I am interested in the use of histamine in the treatment of the migraine type of headache and would appreciate any information and references you can give me on this subject.

M.D., California.

ANSWER.—No reliable reports have been found concerning the treatment of migraine with histamine (Ehrenwald, H.: *Med. Klin.* 31:943 [July] 1935). On the contrary, histamine has been shown to aggravate the condition (Brock, Samuel; O'Sullivan, Mary, and Young, David: *Am. J. M. Sc.* 188:253 [Aug.] 1934). References in textbooks to the use of histamine in migraine are apparently traditional. A few unreported instances have been noted in which histamine has relieved single attacks of migraine.

On the other hand, recent experiments have demonstrated that the mechanism of migraine and histamine headache is somewhat similar (Pickering, G. W., and Hess, Werner: *Brit. M. J.* 2:1097 [Dec.] 1932. Clark, Dean; Hough, Heloise, and

Wolff, H. G.: *Arch. Neurol. & Psychiat.* 35:1054 [May] 1936. Graham, J. R., and Wolff, H. G., *ibid.* 39:737 [April] 1938. von Storch, T. J. C., *ibid.*, to be published). Other investigators have separated from the "migraine-like" headaches a specific syndrome (Horton, B. T.; MacLean, A. R., and Craig, W. M.: *Proc. Staff Meet., Mayo Clin.* 14:257 [April 26] 1939). This "erythromelalgia of the head" might easily be confused with migraine. The headache of this syndrome can be produced by subcutaneous injections of from 0.3 to 0.5 mg. of histamine and in 65 per cent of the cases can be relieved for from two to seventy-two weeks by desensitization with histamine. Apparently typical cases of migraine headache do not respond to histamine desensitization.

No reliable information has yet been presented concerning the part played by histaminase in the production or relief of migraine headache. The Council on Pharmacy and Chemistry has not accepted either histamine or histaminase for use in the treatment of migraine or of allergic conditions in general.

ALBUMINURIA AND HEMATURIA

To the Editor:—A white man aged 37 had severe pain in the lower dorsal vertebrae, radiating around to the front on the right side. He had three severe attacks during the past two weeks, with several lesser attacks during the day and especially on arising in the morning. Two or three years ago he had a similar attack. Each year his insurance company has given him a routine examination and on each of these three yearly examinations his urine showed heavy albumin with numerous red blood cells, with casts. My examination revealed that he weighed 116 pounds (52.6 Kg.). There was no severe tenderness anywhere and no edema of the extremities. The heart and lungs were essentially normal, the blood pressure 120 systolic, 80 diastolic, and hemoglobin 75 per cent. The urine still showed heavy albumin, many red blood cells and only occasional casts (granular and blood casts). A series of roentgenograms revealed no calculi. A retrograde pyelogram showed a normal pelvis on both sides, with an indication of an aberrant renal blood vessel supporting the upper part of the right ureter. The renal function of both kidneys was good as determined by the dye test. The blood urea nitrogen was 17.5 mg. per hundred cubic centimeters of blood. I have placed the patient on a fattening diet and he has gained 10 pounds (4.5 Kg.) in a month. During that time his urine has been about the same, his blood pressure the same, and no edema anywhere. He had two more attacks of pain, not severe at all, mainly in the right loin. What is the diagnosis? Could the aberrant blood vessel cause all this trouble or could the patient have a nephritis, perhaps a focal nephritis of three or more years' standing? I would greatly appreciate whatever help you can offer me as to diagnosis and treatment or further examination.

M.D., New York.

ANSWER.—The history of albuminuria, hematuria and cylindruria for at least three years strongly suggests an active chronic diffuse glomerulonephritis in spite of the normal blood pressure and apparently good renal function. The diminished hemoglobin and possibly elevated blood urea nitrogen would fit in with this diagnosis. Determination of renal function by the urea clearance test or the fifteen minute phenolsulfonphthalein test may reveal definite impairment. Normal results would not necessarily rule out a diffuse nephritis.

Focal glomerulonephritis is best not diagnosed unless the patient has bacterial endocarditis or some other generalized infection or known bacterial focus. A duration of focal nephritis of three years or longer in the absence of an obvious systemic infection would be most unusual. Focal suppuration in the kidneys, including tuberculosis, might produce some of the symptoms shown by the patient but is apparently ruled out by the absence of pus in the urine and by the normal pyelograms. It is assumed that the patient is in good general health and has no hemorrhagic diathesis and no signs of leukemia.

The attacks of pain, however, could scarcely be explained as part of a chronic diffuse nephritis. They would fit in with pressure from an aberrant renal blood vessel. In this connection one would like to know whether on ureteral catheterization the urines from two kidneys were equally abnormal. Should the albuminuria and hematuria be limited to the right side, the diagnosis would be simple and exploratory operation indicated. The fact that both the pain and the urinary abnormality date back some three years may mean a common etiology, namely the aberrant vessel.

It is conceivable that the attacks of pain are entirely unrelated to the right kidney or ureter. They may arise from arthritis of the lower dorsal spine, from postural or other muscular strain, from gallbladder disease, from an atypical penetrating peptic ulcer or from tumors of the spinal cord. None of these need be considered seriously until the urinary tract has been ruled out as the source of pain. However, they should be eliminated by the appropriate diagnostic methods before exploratory operation is performed on the right kidney. If surgery is postponed because of the disappearance or mildness of the attacks of pain, the patient should be followed closely for any further developments.

MEASURING CIRCULATION TIME

To the Editor:—I should like to inquire as to the technic and preparation of materials in the saccharin and ether tests of the circulation time. I have used decholin but would prefer a cheaper method. Is there a relatively inexpensive apparatus to test the vital capacity of patients with heart disease? I have a water metabolism machine (Sanborn) but have not been able to work out any method of measurement.

R. Ned White, M.D., Springfield, Mo.

ANSWER.—The usual technic is to inject a solution of 5 minims (0.3 cc.) of ether in 5 minims of salt solution into an arm vein and observe the time till the subject detects the odor of ether. This has the disadvantage of depending on subjective evidence. Also it measures only the circulation time of the right side of the heart.

Gubner, Schnur and Crawford (*J. Clin. Investigation* 18:395 [July] 1939) described a method which involves filling a spirometer with carbon dioxide and inhaling quickly from it after a forcible exhalation. Time was taken from the beginning of the inhalation to the onset of a sensation of warmth over the head (subjective) or quickened respiration (objective). Results check well with the ether and cyanide methods.

Stanojevic (*Ztschr. f. Kreislaufforsch.* 30:521 [July 15] 1938) used lobeline intravenously, from 6.03 to 0.07 mg. per kilogram. The objective end point is an involuntary cough.

The objective end point is an involuntary cough. In the saccharin test 2.5 Gm. of soluble saccharin is dissolved in 2 cc. of distilled water. The injection is made in an arm vein and the end point taken when a sweet taste is detected.

Baer and Slipakoff (*Am. Heart J.* 16:29 [July] 1938) gave a summary of comparative results by various methods. The article should be consulted for more details. Warren E. Collins and the Harvard Apparatus Company both put out a spirometer of convenient design for the purpose. Any instrument supply company should be able to refer to other sources of convenient machines.

WEAKNESS AND DIZZINESS

To the Editor:—A white woman aged 51 complains of extreme weakness and dizziness on assuming a sitting position of three minutes' duration. Three months ago she first noticed weakness, shortness of breath and dizziness, most prominent on slight exertion and on assuming a sitting or standing position after being in a prone position for some time. The physical history is negative except for an uncomplicated miscarriage twenty-one years ago and mild appendicitis followed by appendectomy, with no complications, ten years ago. The patient has been having mild hot flashes and hypomenorrhea for the last six months, which has responded well to four injections of theelin given during the last two weeks, 10,000 units. The extreme weakness and dizziness have been accompanied by bradycardia varying from 50 to 65. The family history is negative except that a brother died in early youth from diabetes. No other familial diseases were indicated. The patient is fairly well nourished, weighs 135 pounds (61 Kg.) and evidently is extremely weak. She complains of dizziness on assuming the sitting position. She is able to walk for short distances. However, it seems that exertion causes weakness and dizziness. She has been practically bedridden for three months. Examination of the chest reveals nothing abnormal except a bradycardia of 60, increasing to 64 on slight exertion. There are no arrhythmias, murmurs or cardiac enlargement. The chest is negative. The vagina and rectum are normal. Repeated analyses are all negative. The blood count is as follows: red blood cells 00,000, white blood cells 5,000, hemoglobin 84, 13.4 Gm. No abnormalities are seen in the size or shape of the red blood corpuscles. The assermann test was negative. The low white cell count has been peated and runs between 5,000 and 6,000, with normal differential counts. The patient has always been an active woman. Mentally she seems to be perfectly normal. An electrocardiogram reveals nothing except bradycardia and low amplitude. The patient has had four ampules of theelin in the last two weeks which has helped her hot flashes but has done little, apparently, for the extreme weakness and dizziness. I have made a diagnosis of partial heart block and have given a few doses of atropine with no results as yet. Ophthalmoscopic examination of the retina to get any results as yet. The blood pressure is 140 systolic, 90 diastolic. I would appreciate any suggestions you may have to offer in this case.

Fagan N. White, M.D., Russell, Kan.

ANSWER.—A more accurate definition of the term "dizziness" would serve to limit the field of investigation in this case. If the dizziness is a true vertigo, the cause must be sought for in the labyrinth or the central nervous system. Brain tumor is a remote possibility. The determination of a labyrinthine vertigo is a rather highly specialized procedure, as is cerebral localization. The caloric tests, the rotational nystagmus and the other criteria that are useful in such investigations may be found in any standard textbook of neurology. The ophthalmoscopic examination should be extended to include observation as to the presence of papilledema.

If the conditions mentioned can be ruled out, the diagnosis of partial heart block is an attractive one but is difficult to defend in the presence of a normal electrocardiogram. Repetition of the electrocardiogram might prove helpful.

A disorder of the carotid sinus mechanism certainly falls within the range of probabilities. The giddiness and weakness plus the bradycardia point in that direction. Such a disorder might result from a carotid sinus tumor or from pressure on the sinus from without. Circulatory changes in the sinus might be responsible. If the carotid sinus mechanism is at fault, the symptoms should be reproduced or greatly exaggerated by digital pressure over the sinus. Such a maneuver should be carried out with great care and preferably under electrocardiographic control.

One of the myasthenias might be suspected. This seems unlikely with a blood pressure of 140/90, but the response to ephedrine or prostigmine might be worth investigating. Lastly, a menopausal neurosis must be considered. This possibility should be held in reserve until all other possible causes are eliminated.

FETAL DEATH WITH LIVER RUPTURE

To the Editor:—A white obese woman, aged 34, engaged my services to deliver her sixth child. Clinical examination at the fourth month of gestation was essentially negative, serologic study was negative; her past obstetric history was negative. The antepartum course was uneventful; she gained 15 pounds (7 Kg.) in the four months she was observed. Exactly one month before she went into labor (she weighed at this time 238 pounds, or 128 Kg.) she fell down a flight of stairs with sufficient violence to sustain a mild cerebral concussion. The fetal heart was not changed directly after or in the following weeks in its rate, rhythm or intensity. Labor was not extraordinary. The first stage lasted six hours. The membranes were ruptured at full dilatation artificially, and meconium stained amniotic fluid escaped. The second stage lasted fifteen minutes and ended with the spontaneous delivery of an 8 pound 14 ounce (4,065 Gm.) male child in left occiput anterior position. The birth of the child was followed by a second gush of meconium stained amniotic fluid. There was no prolapse of the cord or winding of the cord around the neck. The child cried spontaneously but instead of turning rosy pink became peculiarly cyanosed. From the neck up it assumed a dusky hue, as if one had sprayed the child's face and neck with purple powder. The neck down it became dead white. Respirations were rapid, with a feeling of resistance as if a mass was present. It was felt that the child had suffered some injury, probably prenatal. The child lived for eleven hours. A blood smear done immediately after death showed almost 90 per cent nucleated red blood cells. There were no abnormal white blood cells. Autopsy, limited to the thorax and abdomen, done twenty-eight hours after death, revealed marked pallor of the muscles and hemoperitoneum. The liver was enlarged downward 3 fingerbreadths below the costal margin, and to the left it extended and abutted against the spleen. On the dome of the right lobe there was a laceration about 1 inch long. Near the edge of the same lobe was a smaller laceration covered with some organized blood clot. The cut surface of the liver was pale and anemic. The spleen showed a laceration beginning at the splenic notch and extending toward the hilus. Could such extensive lacerations have resulted from the violent fall to which the mother was subjected? If it was a prenatal event, why did the child not die in utero?

Maurice Schreiber, M.D., Brooklyn.

ANSWER.—It is unlikely that the trauma to which the patient was subjected a month before delivery contributed to the death of the infant. In all likelihood the delivery was responsible for the pathologic changes which led to the fetal death. Rupture of the liver with a fatal hemorrhage is not especially rare in breech deliveries, but it is exceedingly uncommon in cephalic presentations. Normal, natural delivery can result in serious and even fatal trauma to the infant.

The blood smear showing almost 90 per cent nucleated red blood cells is of interest. Normally at term few nucleated cells are present. This finding may be indicative of erythroblastosis, but one cannot make a diagnosis of this condition on a single blood smear. This condition, even though it was present, could not have contributed to the pathologic changes found at necropsy.

GASTRO-ENTERITIS IN CANAL ZONE

To the Editor:—A highway engineer tells me that newcomers to the Panama Canal Zone suffer from some form of gastro-enteritis which is said to be caused from vegetables grown in this area. Fruit and vegetable supplies must therefore be shipped in from the United States. Is this true and, if so, what is the etiologic factor involved?

D. L. Evans, M.D., Manhattan, Kan.

ANSWER.—Each year, at the beginning of the dry season, there appears in the Colon-Cristobal area on the Atlantic side of the Isthmus an epidemic of a mild type of gastro-enteritis, the cause of which has not been satisfactorily determined. A prevalent belief there is that it is caused by sewage-polluted ocean spray, brought inland by the strong trade winds of that season; steps are now being taken to relocate the sewer outfalls of those cities to deeper water in another location where it will be less affected by the winds. Other parts of the Isthmus do not have these epidemics at corresponding times. This gastro-enteritis does not affect chiefly the newcomers but occurs generally among the native population and other long-time residents of the Isthmus in that area.

There is apparently no ground for believing that the vegetables are at fault. The local Chinese gardeners supply a considerable part of the fresh vegetables eaten there, but they are by no means able to supply all, nor are some of their products, lettuce and tomatoes especially, equal in quality to those raised in the United States. For these reasons most of such products are brought in from the United States for the Canal Zone market and for the better trade in Panama and Colon. The Chinese gardens are inspected regularly and frequently by the health department and, of course, human excreta are not allowed to be used as fertilizer. Animal manure from the stables of the army and the cities is plentifully and cheaply supplied to these gardeners, and there has been no evidence that the practice is dangerous.

In the Republic of Panama, outside the Canal Zone and the terminal cities, conditions are more primitive and the water supplies are not too good; but even from these sources the local population apparently receives relatively few cases of infection. Fruits from the interior are freely eaten, and the local citrus fruits, papayas, pineapples and mangoes are highly esteemed. Of course, other fruits that are not grown in Panama are brought from the United States, solely because of the demand for them.

HEMATURIA AND PURPURA IN INFECTIOUS MONONUCLEOSIS

To the Editor:—A man aged 25 complained of a feeling of lassitude and sleepiness two weeks before admission to the hospital. Several days later he complained of generalized aching, which was treated for "grip." These complaints continued unabated along with increased perspiration and slight chills, when suddenly he passed bloody urine and simultaneously broke out with small pinpoint purpuric spots in the skin and the mucous membranes. A moderate generalized adenopathy, most marked in the posterior triangle of the neck, and a palpable spleen were found and the patient was sent to the hospital with a provisional diagnosis of acute leukemia. Physical examination revealed no further abnormalities. On admission the urine was loaded with red blood cells and the albumin was 4 plus. Blood examination revealed hemoglobin 84 per cent, red blood cells 4,330,000, white blood cells 16,400, polymorphonuclear leukocytes 6 per cent, small lymphocytes 77 per cent, large lymphocytes 17 per cent. The lymphocytes did not appear normal although no definite young forms were seen. The next day examination revealed hemoglobin 87 per cent, red blood cells 4,640,000, white blood cells 20,000, platelets, 4,640, polymorphonuclears 6 per cent, small lymphocytes 88 per cent, large lymphocytes 6 per cent. Agglutination tests for paratyphoid A and B, *Brucella abortus* and *Bacillus proteus* were negative. The blood culture was negative. The bleeding time was one minute, the coagulation time five minutes. On the following day the white blood count was 12,200, with polymorphonuclears 12 per cent, small lymphocytes 84 per cent, large lymphocytes 4 per cent. The basal metabolic rate was plus 11. The lymphocytes seemed more normal in appearance. Two days later an agglutination test for infectious mononucleosis was done and was positive up to 1:512. The platelets were 90,000, white blood count 9,800 and the Kline 1 plus. The urine was clear. The final diagnosis was infectious mononucleosis. The clinical condition and laboratory studies tend toward improvement although further platelet counts have not as yet been done. The glands are receding and the spleen is no longer palpable. The point in question is the cause of the severe drop in platelets. Could it be explained as a secondary thrombocytopenic purpura due to a severe infection? Have any other cases of infectious mononucleosis been reported in which purpura developed?

Lawrence B. Lazarus, M.D., Fairview, Ohio.

ANSWER:—The occurrence of thrombocytopenia in infectious mononucleosis has received little attention in the literature. In those cases in which the platelets have been carefully observed and recorded they have been found to be normal. Hematuria and purpuric manifestations in the skin occur infrequently as a manifestation of this disease, but unfortunately the platelets are not mentioned in such cases. On theoretical grounds a decrease in the platelets might occur as a direct result of the disease, especially since the granulocytes are occasionally reduced to a low level. Apparently no cases similar to this one have been reported.

LIPOCAIC FOR PSORIASIS

To the Editor:—A recent newspaper article referred to a new hormone treatment for psoriasis which was reported by Dr. Lester R. Dragstedt at the Federated Biological Societies. Can you give me any information on the subject?

M.D., Texas.

To the Editor:—A patient of mine brought me a newspaper clipping referring to the treatment of psoriasis with so-called lipocaic. What is the present opinion of this treatment and can you give me any references?

M.D., Kansas.

ANSWER:—Lipocaic is the name given by Dragstedt and his co-workers to a substance which, they report, may be a new pancreatic hormone concerned in some way with the normal transport and utilization of fat and which they obtained in an alcoholic extract (insulin-enzyme free) of the gland; the properties and uses of lipocaic are still in the stage of experimental

investigation. Although the use of this substance in psoriasis has been reported to be encouraging, it is not commercially available as yet and has not been licensed for distribution by the Food and Drug Administration nor has it been accepted by the Council on Pharmacy and Chemistry. A list of references follows:

EYE INJURY FROM RUBBING ALCOHOL

To the Editor:—Will you please give me your opinion as to possible injury to the eye from the use of rubbing alcohol composed of a specially denatured alcohol No. 23-H, sucrose octa-acetate, methyl ionone, ionone ketone, and oil of wintergreen, synthetic, U. S. P. The specially denatured alcohol No. 23-H is denatured under government supervision as follows: To each 100 gallons of ethyl alcohol 190 proof is added 8 gallons of acetone and 1½ gallons of methyl isobutyl ketone. A patient at one of the local hospitals alleges injury to the eye from rubbing alcohol, claiming that it induced glaucoma and chronic conjunctivitis of the lids, which resembles trachoma. I am unable to give at this time the exact amount of the chemicals listed, but it would be in the proportion used in rubbing alcohol, and mostly for the odor. I have been asked by the insurance company to give my opinion and would be glad if you could assist me to arrive at the conclusion as to how much injury could be caused by chemicals used in this way and in the probable proportions found in rubbing alcohol.

M.D., California.

ANSWER:—It is somewhat difficult to answer the inquiry concerning the possible injury to the eye from the use of rubbing alcohol without knowing all the details. The quantity of the material in the eye together with the length of time which it remained in the conjunctival sac has a great deal to do with just how much injury might occur. It is definitely known that with rubbing alcohol, which is about a 70 per cent absolute ethyl alcohol by volume, the epithelium of the conjunctiva and cornea may be entirely denuded. If the solution is allowed to remain in the eye after such change has taken place there may be actual fixation of corneal cells in the stroma. With the burning sensation which this solution causes in the eye it seems reasonable to believe that attempts would be made to flush the solution out of the eye immediately. This in itself would tend to prevent any serious consequences. It would seem that the claim that such a solution caused glaucoma and chronic conjunctivitis would be most difficult of proof.

MASSAGE

To the Editor:—Can you tell me where I can obtain information relative to the methods of massage used in relieving pain in the back?

M.D., Michigan.

ANSWER:—It is suggested that for detailed information the following books should be consulted:

- Bankart, A. S. B.: *Manipulative Surgery*, London, Constable & Co., Ltd., 1932.
Mennell, J. B.: *Massage, Its Principles and Practice*, ed. 2, Philadelphia, P. Blakiston's Son & Co., 1920.
Barker, L. F.: *Backache*, Philadelphia, J. B. Lippincott Company, 1931.
Mennell, J. B.: *Backache*, Philadelphia, P. Blakiston's Son & Co., 1931.
Mennell, J. B.: *The Science and Art of Joint Manipulation*, Philadelphia, P. Blakiston's Son & Co., 1939.

Particular reference should be made to chapter 1 of Mennell's textbook on "The Science and Art of Joint Manipulation," in which it is stated: "Unfortunately the unqualified bone-setter attributed his cures, when they occurred, to phenomena which the qualified practitioner knew could only exist in the imagina-

tion. Some spoke of dislocation where no dislocation was possible, others of a 'little bone' being out of place, in a position where there was no 'little bone,' as anatomical knowledge could prove. Then the untenable claim was made that such imaginary dislocations and displacements had been reduced or restored by manipulation. The advent of x-ray examination has proved that, in the vast majority of cases in which claims of this type were made, no dislocation, as understood by the medical practitioner, was in fact present."

PROBABLE ARTERIOSCLEROTIC EPILEPSY

To the Editor:—A man aged 55, a plumber, has had "fainting spells" for about eighteen months with no other symptoms or complaints. Lately the spells have become associated with dyspnea, belching and bilateral tonic contractions of the legs and arms. The blood and spinal fluid Kahn reaction and the colloidal gold curve are negative. There is a marked arteriosclerosis with a systolic apical murmur. The eyegrounds are normal except for sclerosis. The pupils are small, round and fixed and do not react to light but do react in accommodation. The teeth are poor, with several abscesses. The tongue is moderately coated, with no deviation. During attacks the eyes are deviated to right and upward with some reflexes in the toes are normal. The tendon reflexes are normal and phonus elicited at times. Romberg's sign, finger to nose and fixed and do not equal. Sensation appears normal. The attacks have been more frequent in the last two weeks after some improvement under vitamin and phenobarbital therapy. Blood count, hemoglobin and urinalysis were negative. Attacks come on occasionally in sleep and have ceased to be controlled by phenobarbital, oral sodium 5 grains (0.3 Gm.) or dilantin sodium. Lately there has been some headache and fullness in the ears. The patient's mental background is poor and there appear to be some family difficulties. The wife is considered by the patient to be unfaithful and he appears to have a conflict of some sort about his son, who is 5 years old and whom he admires. His wife says he is afraid he will die in one of these attacks and leave the boy. While the attacks have the appearance of hysteria, he has fallen several times in water filled ditches and on several occasions cut his lip or face. I would appreciate any suggestions as to further diagnosis and treatment.

C. W. Atherton, M.D., Marshall, Ill.

ANSWER.—The patient probably has an organic convulsive state syndrome. Because of the generalized arteriosclerosis and retinal sclerosis it is probable that he has arteriosclerotic epilepsy. He should have a detailed and competent neurologic examination with a visual field study every 15 degrees and an x-ray examination of the skull. In this way it will be possible to determine the presence of any abnormal neurologic signs as well as any abnormal skull markings which may make for a diagnosis of a cerebral neoplasm. If there are any abnormal pressure it is suggested that the patient have an encephalogram made. Are there any signs of lead poisoning? All abscessed teeth should be removed. If no other evidence of organic disease of the brain is found, the following treatment is suggested: 1.3 Gm. (20 grains) of sodium bromide three times daily, to be increased to 1.6 Gm. (25 grains) three times daily if attacks continue to occur. He should be kept on this medication for several years. He should be reexamined neurologically every three weeks. He should not be permitted to drive a car, go in swimming or climb any heights.

TREATMENT OF SNAKE BITE

To the Editor:—Would you please furnish information regarding the most modern methods of snake bite treatment with particular reference to suction devices to be applied to the bite after incision and antivenom therapy. I am situated in a tent camp on Hilton Head Island, S. C., where the prevalent snakes are rattlesnakes (diamond back), copperheads and moccasins. We do not have a powerful enough electric generating plant to use any electric suction devices. Is there any advantage in using such devices as suction cups, which were formerly used in the "cupping" treatment of inflammation? Marshall Cohen, M.D., Parris Island, S. C.

ANSWER.—A brief statement on modern methods of snake bite treatment must necessarily omit many qualifications and therefore be inadequate. However, the treatment of snake bite is in general of two kinds: (1) local, designed to delay the spread of venom from the site of the bite to vital organs and to remove as much as possible before it is absorbed, and (2) general, designed to neutralize the absorbed venom and to prevent or minimize its effects.

Under local treatment the use of a tourniquet is still advised, although recent investigation raises the question as to whether it really does much good. Short, deep incisions over the fang marks and multiple incisions through the skin around the edge of the swelling are also advised, supplemented by application of suction. There are several suction devices on the market. Local treatment having been initiated, specific antivenom therapy is undertaken to combat the general effects of the venom in the body. Antivenin is injected intramuscularly or subcutaneously above the tourniquet. If an ample supply of anti-

venin is at hand, part may be given near the bite to help combat local effects. Antivenin should be given as soon as possible after the bite. The longer the time elapsing before injection is given, the larger the dose should be.

The Council on Pharmacy and Chemistry has accepted a North American (Crotalus) and a Tropical American (Bothrops) brand of antitoxin for inclusion in N. N. R. but recognizes that the total dose administered in each case is less likely to prove beneficial in amounts less than 50 cc. In general, individual doses of 10 cc. each are administered until a satisfactory response is obtained. Children usually require a greater total dose than adults (Ditmars, R. L.: Snake Venom Poisoning, in Textbook of Medicine by R. L. Cecil, Philadelphia, W. B. Saunders Company, 1937).

Of general measures apart from antivenin, sedatives such as morphine sulfate to relieve severe pain are indicated. With collapse, stimulants are indicated. Alcohol is regarded by many as injurious, as it hastens the absorption of venom. Infusion of large amounts of physiologic solution of sodium chloride or, better still, blood transfusion will bring great relief and is often life saving in borderline cases.

SIXTH LUMBAR VERTEBRA

To the Editor:—In Queries and Minor Notes, April 6, 1940, on page 1395 of The Journal, appears a question concerning the frequency of occurrence of six lumbar vertebrae, and only eleven pairs of ribs, submitted by "M.D., New Jersey." An answer of "no available statistics" is given. Martin's Lehrbuch der Anthropologie, 1928, page 1076, presents the following regarding the incidence of eleven pairs of ribs:

Number of Cadavers	Stock	Incidence of 11 Pairs of Ribs, per Cent	Investigator
524	European	0.5	Fischel
680	European	0.3	Rabl
908	European	0.9	Bardeen
181	Japanese	1.1	Hasebe

In an article by Prof. Mildred Trotter of this department (The Vertebral Column in Whites and in American Negroes, Am. J. Phys. Anthropol. 13:95) the incidence of six lumbar vertebrae is given as 6.8 per cent, or thirteen times, in 189 skeletons investigated from the skeletal collection of the Washington University Department of Anatomy.

Raymond R. Lanier, Ph.D., St. Louis.

To the Editor:—In your reply to the question regarding anomalies of the vertebral column in The Journal, April 6, 1940, page 1395, your correspondent should be advised to consult the following article, which contains the requested statistics, a full bibliography on the subject: Lanier, Raymond R., Jr.: The Presacral Vertebrae of American White and Negro Males, Am. J. Phys. Anthropol. 25:341-420 (Oct.-Dec.), 1939. According to the figures contained in this article, from two to four white males out of every hundred may show an extra thoracolumbar vertebra, with or without ribs. Among Negro males from 1 to 3 per cent of the usual number of thoracolumbar vertebrae and none with less than the usual number of thoracolumbar vertebrae and none with less than the usual number. Since one of the most distinguishing features of a thoracic vertebra is the facets for articulation with the ribs, the absence of ribs, and consequently also the absence of costal facets on the transitional thoracolumbar vertebra, for all practical purposes makes it a lumbar vertebra.

T. D. Stewart, M.D., Washington, D.C.

INJURY TO NERVES AT ELBOW

To the Editor:—In Queries and Minor Notes, Jan. 27, 1940, page 346, a physician wrote concerning a patient having flexure of the fourth and fifth digits, atrophy of the dorsal interossei, and tenderness in the region of the medial epicondyle. The answer given was that the patient apparently suffered an injury to the radial nerve. According to Gray's Anatomy, on page 459, and verified by dissections, the fourth and fifth digits are flexed at the metacarpophalangeal joints and extended at the interphalangeal joints by the lumbrical muscles, which are supplied by the ulnar nerve. The dorsal interossei are also supplied by the ulnar nerve, which lies behind the medial epicondyle. The radial nerve, in the elbow area, lies in the cubital fossa and could not possibly have been injured in knocking the elbow. In short, the clinical picture is typical of an ulnar nerve injury at the medial epicondyle. John A. DiFiore, Omaha.

HERPES ZOSTER OF SUPRA-ORBITAL DIVISION OF FIFTH NERVE

To the Editor:—In Queries and Minor Notes in The Journal, March 9, 1940, there was an inquiry about the treatment of herpes zoster of the supra-orbital division of the fifth nerve. Of the treatments mentioned, one which I feel would be especially applicable in this condition has been omitted. The treatment I have in mind is the one for trifacial neuralgia advocated by Dr. Benjamin Ulanski of Philadelphia in which he utilizes the rapid sinusoidal current and which has been successful in a large number of cases. The treatment appears to be simple and efficient, and leaves no after-effects.

Leon Felderman, M.D., Philadelphia.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in *The Journal*, June 8, page 2325.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II, June 17-19. Part III, June or July, to be given in medical centers having five or more candidates desiring to take the examination. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: December 1940. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written*. October 21. Applications must be on file by September 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral*. Cleveland, Oct. 5. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Written*. New Orleans, January 1941. Final date for application is September 15. Sec., Dr. Fremont A. Chandler, 611 Poydras St., New Orleans.

AMERICAN BOARD OF PEDIATRICS: *Written*. November 17, preceding the annual meeting of the American Academy of Pediatrics. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF SURGERY: *Oral*. Part II. Chicago, June 18-19. *Written*. Part I. Various centers, October 21. Final date for filing application is September 15. Sec., Dr. J. Stewart Rodman, 225 S. Fifteenth St., Philadelphia.

Colorado January Report

Dr. Harvey W. Snyder, secretary, Colorado State Board of Medical Examiners, reports the written examination held at Denver, Jan. 3-5, 1940. The examination covered eight subjects and included sixty-eight questions. An average of 75 per cent was required to pass. Three candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1938)	80	
Creighton University School of Medicine.....	(1939)	81	
Osteopath*		76	

Three physicians were licensed by endorsement on January 2. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
University of Kansas School of Medicine.....	(1933)	N. B. M. Ex.	
Tufts College Medical School.....	(1931)	Maine	
University of Tennessee College of Medicine.....	(1935)	Tennessee	

* Examined in medicine and surgery.

Hawaii January Examination

Dr. James A. Morgan, secretary, Board of Medical Examiners, Territory of Hawaii, reports the written examination held at Honolulu, Jan. 8-11, 1940. The examination covered ten subjects and included eighty questions. An average of 75 per cent was required to pass. Two candidates were examined, both of whom passed. Two physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of California Medical School.....	(1936)	90	
McGill University Faculty of Medicine.....	(1938)	86.1	

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Harvard Medical School.....	(1934), (1937)	N. B. M. Ex.	

Maine March Examination

Dr. Adam P. Leighton, secretary, Maine Board of Registration of Medicine, reports the written examination held at Portland, March 12-13, 1940. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Fifteen candidates were examined, thirteen of whom passed and two failed. Four physicians were licensed by reciprocity and two physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
The School of Medicine of the Division of Biological Sciences	(1938)	83	
Boston University School of Medicine.....	(1939)	81	
Harvard Medical School.....	(1933) 82, (1935)	81	

Tufts College Medical School.....	(1938) 82, (1939)	80, 85	
University of Rochester School of Medicine.....	(1938)	84	
Hahnemann Medical College and Hospital of Philadelphia.....	(1939)	80	
McGill University Faculty of Medicine.....	(1939)	78	
Ludwig-Maximilians-Universität Medizinische Fakultät, München	(1911)	77	
Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät, Bonn	(1933)	75	
Universität Zürich Medizinische Fakultät.....	(1938)	81	

School	FAILED	Year Grad.	Number Failed
Tufts College Medical School.....	(1932)		1
Georg August-Universität Medizinische Fakultät, Göttingen	(1924)		1

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Tufts College Medical School.....	(1935)	New Hamp.,	
University of Rochester School of Medicine.....	(1939)	Ohio	
Jefferson Medical College of Philadelphia.....	(1937)	Penna.

Rhode Island January Examination

Dr. Robert M. Lord, secretary, Rhode Island State Board of Examiners in Medicine, reports the written examination held at Providence, Jan. 4-5, 1940. The examination covered twelve subjects and included seventy-five questions. An average of 80 per cent was required to pass. Six candidates were examined, all of whom passed. One physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Georgetown University School of Medicine.....		86	
University of Buffalo School of Medicine.....		84.1	
University of Oklahoma School of Medicine.....		91.1	
University of Toronto Faculty of Medicine.....	(1938) 89.6	84.9,	

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Harvard Medical School.....	(1934)	N. B. M. Ex.	

South Dakota January Examination

Dr. J. F. D. Cook, director, Medical Licensure, State Board of Health, reports the written examination held at Pierre, Jan. 16-17, 1940. The examination covered thirteen subjects and included 100 questions. An average of 75 per cent was required to pass. Three candidates were examined, all of whom passed. One physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Rush Medical College.....	(1938)	84.7, 88.8	
University of Manitoba Faculty of Medicine.....	(1936)	85.8	

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
University of Minnesota Medical School.....	(1935)	N. B. M. Ex.	

West Virginia March Examination

Dr. Arthur E. McClue, secretary, Public Health Council of West Virginia, reports the oral and written examination held at Charleston, March 4-6, 1940. The examination covered eleven subjects and included 110 questions. An average of 80 per cent was required to pass. Five candidates were examined, all of whom passed. Seventeen physicians were licensed by reciprocity and two physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
St. Louis University School of Medicine.....	(1930)	88.8	
Cornell University Medical College.....	(1923) 87.5, (1937)	88

Book Notices

Orthopedic Operations: Indications, Technique and End Results. By Arthur Steindler, M.D., F.A.C.S., Professor of Orthopedic Surgery, The State University of Iowa, Iowa City, Iowa. Cloth. Price, \$9. Pp. 766, with 322 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1940.

To orthopedic surgeons, this is one of the most welcome books that has appeared in English. Steindler is generally recognized to be one of the leaders of orthopedic surgery in the United States, learned, conscientious and trustworthy. His diagnostic ability, his clear interpretation of indications, his excellent surgical technic, his mature and careful judgment and his truthfulness in stating his end results are conceded and widely praised. Although the book is entitled "Orthopedic Operations," it contains much more than the title indicates, representing an experience of thirty-five years, limited to orthopedic deformities and diseases.

The book is divided into three parts: (1) The indications for various operations, (2) the technic of such operations and (3) the end results following the operations. The author discusses the plans and principles of procedure and the technic of execution and he presents his final judgment not on the operation but on the results. Many operative procedures have been omitted, but only because of mature judgment based on experience.

Steindler establishes the four following principles as guides in evaluating operative procedures:

1. Is the operation rational from the physiologic and mechanical points of view?
2. Does experimental evidence substantiate the expectations of regeneration and repair that are placed in the operation?
3. Is the operative technic consistent with recognized experimental or empirical observations?
4. Are reliable statistics available to justify the procedure, in view of the definite end results?

The first part of the book deals with general surgical facts and representative approaches to general operations. Next come the operative procedures on the structures of the motor and locomotor system, and third the precise clinical situations in which these operations should be applied. The author has compiled an enormous amount of data, a large number of appropriate photographs and other types of illustrations. He has had a number of excellent assistants such as Waring, Ruhlin, Milgram, Kulowski, Freund and Luck; the advantage of the large experiences of his colleagues in the departments of the University of Iowa and a close and prolonged association with Professor Prentiss in the department of anatomy of the university.

The chapter on the biology of functional restoration is excellent. Special surgical risks are discussed from the point of view of constitutional and local complications. The section on choice of anesthesia is good.

The various sections on tendons make a classic monograph in themselves. The author describes Chandler's operation for transplantation of the patellar tendon but does not give the latest modified technic. There is a section on operative indications and end results in chronic arthritis and another on disabilities due to nerve disorders. Steindler also presents the operative indications in the various types of bone tumors and tumors of the soft tissues, using the diagnostic chart of Geschickter and Copeland.

Some of the most carefully thought out chapters concern poliomyelitis, spastic paralysis, congenital deformities, scoliosis, traumatic lesions, back conditions and tuberculosis. This book is a mine of material based on a wealth of experience and extensive knowledge. The medical profession is fortunate in having a work so scholarly in its development and one which could come only from such a rare combination of knowledge with a talent for the correlation of vast material. Certainly, this book is one which must be on every orthopedic surgeon's desk.

Hospital Public Relations. By Alden B. Mills. Cloth. Price, \$3.75. Pp. 361, with 16 illustrations. Chicago: Physicians' Record Company, 1939.

At last the much neglected field of public relations for hospitals has been charted. This volume should be studied carefully by every hospital trustee and administrator. Mills has made a distinct contribution not only to the field of hospital administration but to the advancements being made in providing hospital and medical care to the American people. This book will provide the alert trustee and administrator with workable plans for making the public better understand their hospital and should arouse those who have been less observing of modern trends and needs to an awareness of the role public opinion will assume in the future of their institutions.

Mills defines a public relations program, as the term is used in his book, to mean one that "is a conscious, sincere, directed endeavor to create and strengthen contacts which contribute to the development of mutual understanding, good will and respect between an institution (or business) and its public."

The book is divided into two sections. The first one, dealing with general considerations, discusses such subjects as the influencing of public opinion, the principles of public relations, what constitutes good hospital service, various phases of the problem of cost to the patient, and where the responsibility rests for a public relations program. In the second section the application of methods is described. This ranges from personal contacts with hospital personnel and their part in the program to expositional methods such as annual reports, house magazines, letters, pamphlets, bound books, newspapers, magazines and visual and auditory technics, including exhibits, motion pictures, dramas, pageants, public meetings and the radio. Fund raising campaigns, joint public relations programs with various agencies associated with the hospital field and a discussion of the finances of a public relations program also are included in this section.

The chapter on newspapers and magazines deserves the careful study of all hospital administrators, whether or not they have or contemplate a formal public relations program. Mills's discussion of how to get along with the press is sound and offers advice that can well be heeded by all persons who have, or should have, any contacts with newspapers. A valuable feature of the book is the five appendixes dealing with how to evaluate quality in hospitals, the function of a woman's auxiliary, the policy on fund solicitations by institutions, giving information to the press, and approved motion pictures. Throughout the book are valuable examples of how various hospitals and organizations in or allied to the hospital field have approached and solved some of their public relations problems. Of particular interest are the outlines of some of the public relations activities of the hospital and medical associations and how they can be correlated with individual hospital programs. An index makes instantly available the wealth of data the book contains.

The Specific Therapy of the Pneumonias. By Jesse G. M. Bullowa, M.D., Clinical Professor of Medicine, New York University College of Medicine, New York, Beaumont Lecturer for 1939. Reprinted from The Journal of the Michigan State Medical Society, July-August, 1939. Cloth. Price, \$1. Pp. 80, with illustrations. Detroit: Lectureship Foundation Committee of the Wayne County Medical Society, 1939.

This little volume contains the Beaumont Lecture delivered before the Wayne County Medical Society on Feb. 20, 1939. It is divided into two parts: first "The Choice of a Remedy" and second "Serum Therapy of the Pneumonias."

In part 1 the author reviews the difficulties of evaluating new therapies in the pneumonias. A large variety of therapeutic agents—quinine, ethylhydrocupreine, specific and nonspecific vaccines, diathermy, x-rays, deuteroproteose (Brooks) and pneumothorax, each of which in turn has been heralded in recent years as a panacea in the treatment of pneumonia, are noted as illustrations of the extreme caution which must be exercised in evaluating these remedies. Many of the pitfalls in the clinical evaluation of pneumonia therapy are revealed. Emphasis is placed on the importance of presenting the necessary basic data on which mortality in pneumonia depends. These would include the etiologic agent and the serologic "type" where the pneumococcus is involved, the results of blood cultures, the age of the patients, the stage of the disease when treatment is begun, and so on. The difficulty of carrying over the results of test tube or animal experimentation to the therapy in human cases is also illustrated by well chosen examples.

The lecture was delivered during the time when the interest of the medical profession and of the lay public was sharply focused on sulfapyridine. Studies which Osgood, in collaboration with Bullowa, carried out with bone marrow cultures had indicated that the combination of specific serum and sulfapyridine was definitely superior to either of these agents used separately. The author's clinical data at the time covered less than half a year's observations on the use of this drug, whereas his experience with specific serums extended over many years. Nevertheless the striking effect of sulfapyridine treatment of the pneumococcal pneumonias is easily discernible.

All of this forms a background for a discussion of the relative merits of specific serums and sulfapyridine used individually or in combination. The views expressed in this lecture are sound and, as stated in the preface, were still held by the author when the lecture was published at the end of the following summer. The experience acquired since that time may require a slight change in emphasis but no essential deviations from the conclusions reached.

Part II contains a clear, concise, practical and authoritative exposition of specific serum therapy. This section is the more important one because of the author's extensive experience in this field and because, with the attention of the profession focused on chemotherapy, this important phase of the treatment of the pneumonias is only too easily neglected—to the detriment of a good many patients.

The volume is well bound and clearly printed. It contains a number of good photomicrographs of Osgood's bone marrow preparations illustrating the action of serum and sulfapyridine. Numerous temperature charts are also included to illustrate the good clinical results obtained with these agents, as well as some of the failures.

Lehrbuch und Atlas der Haut- und Geschlechtskrankheiten. Von Dr. Karl Zieler. In zwei Bänden—Textband und Tafelband. Fifth edition. Cloth. Price, 60 marks per set. Pp. 700, with 172 illustrations; 196 plates containing 378 colored illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1939.

The work consists of two volumes, one containing the textbook and another containing colored reproductions of wax models. The first volume is divided into the two main subjects cutaneous diseases and venereal diseases. In the section on cutaneous diseases a general discussion including normal anatomy, physiology, general pathology, general diagnosis and treatment is followed by the individual diseases. The manner of description is clear and therefore easily understandable and interesting. This part is arranged for teaching purposes into twenty-one groups which Zieler states may not be satisfactory from a scientific point of view. This would, however, be true with regard to any classification as long as our knowledge of so many conditions is incomplete. The groups are disturbances of keratinization, disturbances of the distribution of pigment, disturbances of the vascular system of the skin, pruritic dermatoses, eczemas, the group containing psoriasis and lichen ruber planus, diseases involving mainly the corium, the group of seboreic dermatoses and the general diseases of the hair follicles and disturbed function and diseases of the sweat glands, diseases of the hair and nails, tumors of the skin, diseases following thermic, mechanical, chemical and actinic agents, toxicodermas, animal parasites, fungous diseases of the skin, diseases caused by protozoa, filtrable and not yet satisfactorily investigated microbes, groups of the leukemias and of the mycosis fungoides, cutaneous diseases due to pus producing microbes, atrophizing chronic inflammations of the skin of unknown cause, and infectious (microbic) granulomas of the skin. The description is confined to what seemed necessary to the author, discussion and more detailed literature being avoided. Thus we find disputable opinions of the author, as with Boeck's sarcoïd, lupus pernio and granuloma annulare, without a discussion of other points of view.

The venereal diseases are also adequately described: syphilis (general cause, syphilis organism and experimental syphilis, immunity in syphilis, transmission of syphilis, character and course in the different stages, variations and locations, congenital syphilis, causes of the varying course of syphilis, diagnosis and examination, prognosis and cure, prophylaxis, treatment), ulcus molle (origin, character and cause, lymphangitis, lymphadenitis), lymphomatosis inguinalis suppurativa (subacute), a name which

he prefers to lymphogranulomatosis inguinalis, granuloma venereum, gonorrhea (the gonococcus, gonorrhea in men, gonorrhea in women, gonorrhoea recti, gonorrhoea conjunctivae et mucosae oris, systemic conditions in gonorrhea, prophyllaxis), nonvenereal diseases (urethritis nongonorrhoeica, balanitis, acute gangrene of the external genitalia, ulcus vulvae acutum).

In the treatment of syphilis the author states that Almquist's method (continued course of treatment changing with courses of arsphenamine and bismuth compounds) may be more efficient in early syphilis but that the chronic intermittent treatment (according to Neisser-Fournier) is more useful in later cases.

In the treatment of gonorrhea the use of sulfanilamide has been a distinct advancement. Its side effects will be less and less as our experience with the drug increases.

The textbook is illustrated by many good drawings, especially the histopathologic pictures.

The colored illustrations are reproduced mostly from models by Kroener of Breslau and also by Baretta of Paris, Johnson and Vogelbacher of Freiburg and Kolbow of Berlin. They are almost without exception beautiful and very instructive. This new edition, as the previous ones, should be useful to medical students and general practitioners as well as to dermatologists.

The Physiological Basis of Medical Practice: A University of Toronto Text in Applied Physiology. By Charles Herbert Best, M.A., M.D., D.Sc., Professor and Head of Department of Physiology, University of Toronto, and Norman Burke Taylor, M.D., F.R.S., F.R.C.S., Professor of Physiology, University of Toronto. Second edition. Cloth. Price, \$10. Pp. 1,872, with 497 illustrations. Baltimore: William Wood & Company, 1939.

The first edition of this book appeared in 1937 and had immediate favor from the medical profession, so that there were many reprints. The second edition has been brought quite up to date. The authors have been prevailed on to add a section on the special senses which did not appear in the first edition; this has greatly enlarged the size of the book. The authors have been helped in some of the special chapters by physicians who have given particular consideration to these departments of physiology. The book is supplemented by bibliographic references both to monographs and reviews and to the periodical literature. By the use of various sizes of type and special arrangements, the authors have been able to distinguish those subjects to which the student should give special attention. Obviously it has not been possible for the authors to keep pace with the very latest materials, as, for example, the most recent work on vitamins and glandular substances. Medicine proceeds so rapidly in these modern times as to make almost any medical book necessary of supplement by periodical literature. However, the authors have made available one of the best practical books on physiology, useful either to the student or to the practitioner of medicine.

Cancer Mortality in the United States. II: Recorded Cancer Mortality in Geographic Sections of the Death Registration States of 1920, from 1920 to 1935. By Mary Gover, Associate Statistician, United States Public Health Service. From the Division of Public Health Methods, National Institute of Health. Prepared by direction of the Surgeon General, Federal Security Agency, U. S. Public Health Service. Public Health Bulletin No. 252. Paper. Price, 10 cents. Pp. 74, with 19 illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1940.

Analyses of the course of recorded mortality due to causes which are producing increasing death rates are necessary to show the size and nature of these problems and the rate at which they are changing. The present study shows clearly the changes that are occurring in cancer mortality, since the rates by classification of the site of the disease for the sixteen years studied are confined to the death registration states of 1920 and are therefore less influenced by the fluctuations that often are found in the expanding death registration area when new states were becoming accustomed to death registration values and technic. The cancer mortality rates are tabulated by age, sex, color and site according to the geographic sections of the death registration states of 1920. In each of these five geographic sections the recorded mortality rate for females is higher than the rate for males, varying from a rate of 125.6 per hundred thousand females in the Northeast section to 60.6 per hundred thousand males in the South for an average of the five years 1931-1935.

For each of the three 20 year age groups, 35-54, 55-74 and 75 years and over, the mortality rate from all cancer is

highest in the Northeast and lowest in the South. Cancer of the "stomach, liver, peritoneum, intestines, rectum" and "other or unspecified organs" formed the major portion of the mortality among males but only slightly above 50 per cent of the total rate for all cancer among females. Among the external sites of cancer it is of interest to note the relatively high rate for cancer of the buccal cavity among Southern females, the high rate for cutaneous cancer among both males and females in the South and the relatively slight degree of variability in the rates for cancer of the female genital organs in all sections studied. Mortality from all cancer is increasing in all sections of the United States. The increase in each section is more rapid among males than among females. The South has shown a slightly higher rate of increase than the other four sections included in the study, and in this section the difference is more marked among males than among females. Mortality from cutaneous cancer shows some decline in most geographic sections; cancer of the breast is increasing; cancer of the stomach and liver has declined more among females than among males; mortality from cancer of the peritoneum, intestine and rectum has increased in all five geographic sections, the increase being generally higher among males than females. Mortality from all cancer among Negroes has increased in both the North and the South and, except for cancer of the peritoneum, intestine and rectum among males, the Negro rate is higher in the Northern section than it is in the South.

This is a purely statistical analysis and no attempt is made to suggest any reasons for the differences observed statistically.

Eighteenth Hospital Yearbook. 1940 Hospital Purchasing File: Directory of Products, Manufacturers' Catalogs, Purchasing Standards and Other Reference Data. Boards. Price, \$2.50. Pp. 1012, with illustrations. Chicago: Modern Hospital Publishing Co., Inc., 1940.

In addition to a well indexed advertising section, there is an administrative section of more than 100 pages containing valuable data on the purchase and use of hospital supplies and materials and on many problems arising in the course of hospital administration. There are chapters on purchasing, storage, drugs and pharmaceuticals, furnishings, mechanical equipment, standards for supplies and fire precautions. A chapter is devoted to a safety program for a hospital. There are check lists that should prove suggestive in purchasing for different departments, and a list of national agencies giving the names and addresses of those agencies serving in the hospital and allied fields. The book closes with current hospital statistics devoted mainly to recent reports, per diem costs and other costs for large groups of hospitals in different sections of the country.

A Study of the Nasopharyngeal Bacterial Flora of Different Groups of Persons Observed in London and South-East England During the Years 1930 to 1937. By Edith Straker, M.B., B.S., D.P.H., A. Bradford Hill, D.Sc., Ph.D., and R. Lovell, Ph.D., M.Sc., M.R.C.V.S. Together with Some Observations on the Occurrence of H. Influenzae in the Trachea. By A. B. Rosher, M.R.C.S., L.R.C.P., D.P.H., and W. T. Cole. Ministry of Health, Reports on Public Health and Medical Subjects No. 90. Paper. Price, 2s. Pp. 131. London: His Majesty's Stationery Office, 1939.

The monograph comprises an important and extensive contribution to the knowledge of the bacterial flora of the respiratory tract. Relatively large groups of human subjects were involved. In some groups the period of observation was relatively short and the number of observations few, but the noteworthy feature is that in a group of from 150 to 200 subjects bimonthly studies of the nasopharyngeal flora of each individual were made continuously for from five to seven years. Further comparisons of the nasal and nasopharyngeal bacterial content over several years' time also were made. It is impossible to discuss the minutiae, but several facts are established: Pneumococci, hemolytic streptococci, meningococci and Haemophilus influenzae tend to establish themselves in the nasopharynx and, in the absence of epidemics, to maintain a relatively distinctive frequency. Carriers may be classified as constant, intermittent or occasional; the number of individuals in which a given species of the organisms is not found decreases progressively as the number of observations increases. Certain seasonal trends are maintained throughout successive years. For instance, carrier rates are lowest in the third quarter of the year and tend to increase with cold damp weather, although the hemolytic streptococcus was isolated more frequently in warm dry weather. In the winter months extension of bacteria to the nasal tract and

the lower respiratory tract increases. It is also interesting to note that approximately 50 per cent of carriers presented only a single type of pneumococcus and in some instances carried only that type for long periods. Nevertheless, considerable interchange of types occurs. No correlation between bacterial flora and common colds was observed. No significant relation of Haemophilus influenzae to outbreaks of epidemic influenza could be established. Details of the studies are clearly presented with extensive tables and incidence curves. The data offer valuable evidence for all students of respiratory disease.

Common Procedures in the Practice of Paediatrics: Being a Detailed Description of Diagnostic, Therapeutic, and Dietetic Methods Employed at the Hospital for Sick Children, Toronto. By Alan Brown, M.D., F.R.C.P., Physician-in-Chief, Hospital for Sick Children, Toronto, and Frederick F. Tisdall, M.D., F.R.C.P., Associate Physician, Hospital for Sick Children, Toronto. Third edition. Cloth. Price, \$5. Pp. 314. Toronto: McClelland & Stewart, Limited, 1939.

The technic of the practice of medicine represents a field which is constantly increasing in scope. This book details the diagnostic, therapeutic and dietetic methods employed in the Hospital for Sick Children in Toronto. Discussion of the procedures employed is not included. Rather, the text presents in a brief form the procedures found to be useful in common conditions in hospital practice. The chapters on history taking in infants and children, feeding the infant and child, and therapeutic and diagnostic procedures are especially valuable because of their simplicity, brevity and practical application. The chapter on difficulties in diagnosis deals with many not uncommon disorders, obtained from a review of hospital records, which offered a problem in etiology. In the present edition new sections have been added on feeding, behavior problems, intelligence tests, eczema and related subjects. The book should be of value to interns and general practitioners for practical reference. In the teaching of medical students it should be relied on only to give them practical details of the common procedures employed in the technic of the practice of pediatrics.

The City of New York. Department of Welfare Report for 18-Month Period January 1, 1938-June 30, 1939. William Hodson, Commissioner. Paper. Pp. 193, with illustrations. New York, 1940.

Every seventh person in Greater New York's 7,000,000 population received some type of aid through the department of welfare during the eighteen months ended June 30, 1939, at a total cost of \$213,345,253. This is an annual expense of about three times the annual expenditures for all purposes of the entire federal government in the decade before the Civil War, for a population of between twenty and thirty million. Jan. 1, 1938, the department of welfare had 11,081 employees, of whom only 10 per cent were civil service appointees. Eighteen months later the staff had dropped to 10,370, of whom 79 per cent were civil service appointees. The burden of relief rose and fell in close direct correlation with unemployment. During the eighteen months \$2,397,296.58 was expended for medical care, of which \$1,527,586.50 was paid to doctors. "We must pay wages to our workers which will enable them to maintain a decent standard of living" is the conclusive recommendation of the report.

Personal and Community Health. By C. E. Turner, A.M., Sc.D., Dr.P.H., Professor of Biology and Public Health in the Massachusetts Institute of Technology, Cambridge. Fifth edition. Cloth. Price, \$3. Pp. 652, with 131 illustrations. St. Louis: C. V. Mosby Company, 1939.

For many years this volume has been one of the standard textbooks used by colleges and universities in classes in personal and community hygiene. The present edition follows closely the organization of the previous editions. The first half of the book is devoted to a discussion of personal health and the latter half to community hygiene. The organization of the material follows closely that of most college textbooks on hygiene, taking up the various bodily processes of digestion, respiration, circulation and excretion from the point of view of physiology and function. Included in the personal hygiene section is a discussion also of the organs of special senses and the hygiene of physical activity and body mechanics. With the exception of a considerable revision of the chapter on nutrition, in which the section on the role of vitamins in nutrition has been expanded, there is little difference between the fifth edition and the fourth edition. The section on community health outlines the bacterial theory of communicable diseases and the

essential facts of immunity. The chapter on the three great plagues tuberculosis, syphilis and the common cold has been rather extensively revised, with particular new material in the discussion of the prevention and treatment of syphilis. It is to be regretted that in this revised edition the tables on maternal and infant mortality rates were not brought down to date, as in the five years since the preceding edition there has been a distinct change in the trend of the maternal death rate. The most important revisions in the book appear to be in the section on school hygiene and industrial hygiene. The chapter on school hygiene is an excellent presentation of the present status and recognized problems of the public health program in the schools and should be of great value to college students who are to become teachers. This book will continue to be a valuable reference and textbook for all those conducting hygiene classes for college students.

Obstetrical Procedures and Practice in Hospitals. Report of the Committee on Maternal Welfare of the Canadian Medical Association. Issued by the Department of Hospital Service of the Canadian Medical Association. Paper. Price, 25 cents. Pp. 41. Montreal, [n. d.].

The purpose of this small book is to help in the further reduction of maternal mortality and morbidity by setting up standards of organization in hospitals accepting maternity cases. It is recognized that the problems of the large and small hospitals are different, and these variations are discussed. The standards of organization include accommodations, clinical facilities, organization of the department, clinical records, conferences, care of the newborn and extramural services. It is believed that the standards established, if followed, will aid materially in reducing maternal mortality and morbidity. Among the important subjects considered are the organization of obstetric staffs to control obstetric procedures, the isolation of patients with infections, and standards for sufficient nursing personnel.

Tables, Factors and Formulas for Computing Respiratory Exchange and Biological Transformations of Energy. Prepared by Thorne M. Carpenter, Acting Director, Nutrition Laboratory, Carnegie Institution of Washington. Carnegie Institution of Washington, Publication No. 303B. Third edition. Paper. Price, \$1. Pp. 142. Washington, D. C.: Carnegie Institution of Washington, 1939.

Carpenter has collected from various sources tables, factors and formulas used by biologists in computing respiratory exchange and the transformation of energy. The fact that three editions of these tables have been found necessary indicates the convenience and value of such a compilation to workers in the general field of energy metabolism.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Evidence: Right of Medical Witness to Testify as to Experiments Not Made by Him.—Two policies of insurance issued by the defendant company on the life of Woelfle provided double indemnity if the insured "died as the result of an accident." Woelfle died from a rupture of the aorta, Sept. 9, 1932. The beneficiary brought suit for double indemnity under the policies, contending apparently that the rupture of the aorta was caused solely by an accidental fall suffered by the insured while playing golf four days before his death. From a judgment for the insurance company the beneficiary appealed to the United States circuit court of appeals, eighth circuit.

At the trial, a medical witness called by the insurance company was permitted, over objection, to testify as to experiments, about which he had read but which he had not personally performed, designed to determine the pressure required to rupture an aorta. On the basis of the results of these experiments he gave it as his opinion that a fall such as the insured sustained could not produce a rupture of the aorta. The beneficiary contended that the testimony referred to "was pure hearsay and incompetent." We do not regard the testimony, said the circuit court of appeals, of this witness as to experiments not made by him as hearsay or incompetent. It is apparent that this physician was testifying as to the accepted learning of his profession

and as to the basis on which his ultimate opinion was given. Medical experts are entitled to base their opinions on the teachings of medical science and are not limited to expressing opinions only as to subjects with which they are familiar through their own observation and experience. A rule which precluded an expert from expressing an opinion based on the teachings of his profession would be unsound and impractical.

At the trial a medical witness called by the beneficiary was asked the following question: "Could there have been a rupture as shown by this slide that started on Monday, Sept. 5, 1932, and have ruptured all the way through on Sept. 9, 1932?" The trial court refused to permit the witness to answer the question because it called for a conclusion and the answer would invade the province of the jury and be a mere speculation. In the judgment of the appellate court the trial court erred in so ruling. The very purpose of calling this witness was to obtain his expert conclusion or opinion as to whether the alleged fall on the golf links could have caused and was the probable cause of the death of the insured. The fact that the witness was asked for an opinion on an issue which the jury would be ultimately called on to decide did not affect the admissibility of his opinion. The court concluded, however, that the error committed by the trial court did not justify a reversal of the judgment because the record showed that this medical witness on cross examination testified that "his theory was that there was a partial rupture of the aorta on the 5th of September that went down to a certain place before it ruptured through on the fourth day" and, furthermore, because the witness on cross examination "described in detail how the slides, which were magnified and thrown on the screen, showed that the aorta had been ruptured through nearly all the way, with only a portion holding until it finally ruptured."

The judgment in favor of the insurance company was therefore affirmed.—*Woelfle v. Connecticut Mut. Life Ins. Co. of Hartford, Conn.*, 103 F. (2d) 417.

Pharmacy Practice Acts: "Proprietary Medicine" Defined.—The Business and Professions Code of California, section 4030, makes it unlawful for any person not a registered pharmacist or a registered assistant pharmacist to manufacture, compound, sell or dispense any drug, poison, medicine or chemical. Heron was convicted of violating this section on evidence that he was not a registered pharmacist or a registered assistant pharmacist and that he manufactured and sold at wholesale and retail a product labeled "Heron's Pure Eucalyptus Oil." He then appealed to the appellate department, superior court, Los Angeles County, California.

Heron contended that section 4032 of the Business and Professions Code, which provides that the prohibition contained in section 4030 "does not apply to registered, trade-marked or copyrighted proprietary medicines, registered in the United States Patent Office," permits him to manufacture and sell his product. But, said the appellate court, the language employed in section 4032 to denote medicines that can be sold by persons not registered either as pharmacists or as assistant pharmacists cannot be interpreted literally without robbing it of effect, because medicines, proprietary or otherwise, may not be registered in the United States Patent Office nor may they be trade-marked or copyrighted. In the judgment of the court the legislature undoubtedly intended to exempt from the prohibition in section 4030 those proprietary medicines which are sold in containers bearing the trade-mark of the manufacturer of the medicine, if the trade-mark is, as it may be, registered in the United States Patent Office. As so construed, if the medicine which Heron sold was proprietary it was clearly within the exception, for its container bore Heron's trade-mark, which he had registered in the United States Patent Office. The only question to be determined, then, was whether or not Heron's product was a proprietary medicine. The court recognized the fact that, strictly speaking, only those medicines which are protected by a patent are patent medicines and that a proprietary medicine can only be one which is protected by a patent, for in no other way can a "proprietor" secure an exclusive right of property in its manufacture. Nevertheless it believed that the term "proprietary medicine" as used in the section referred to was

used in a popular sense. Whether or not a product is a patent or a proprietary medicine in a popular sense is dependent not on the fact that it is protected by a patent nor that its maker actually has a secret formula or process but on the dress in which it is offered to the public. Unprotected by a patent, and even though others may actually be manufacturing the same article, a medicine is commonly referred to as a patent or proprietary medicine if its proprietor gives it a trade-name, or his name, offers it to the public as his product, puts it up in a distinctive container and expressly or impliedly claims special virtue for it because of the alleged special formula, skill or care which goes into its manufacture. As was said by the Supreme Court of Arkansas in *Riggs v. City of Hot Springs*, 181 Ark. 377, 26 S. W. (2d) 70:

... where any article intended to be used for medicinal purposes is prepared from a secret formula and is placed in containers, either packages or bottles, for sale, to be used without further preparation, and is labeled so that it may be for immediate use, it is a matter of common knowledge that such remedies are called "patent" or "proprietary" medicines.

For the reasons stated, the appellate court held that "Heron's Pure Eucalyptus Oil" was a "proprietary medicine" not subject to the prohibitions of the pharmacy practice act. The court accordingly reversed the judgment of conviction.—*People v. Heron (Calif.)*, 90 P. (2d) 154.

Charitable Hospitals: Liability Insurance as Affecting Liability to Pay Patient.—The defendant university, an eleemosynary, nonprofit corporation, among other things operates a hospital in which both charity patients and pay patients are treated. The plaintiff was admitted as a pay patient to the defendant's hospital in an irrational and delirious condition. To prevent his getting out of bed 11 inch sideboards were placed thereon. When he was alone in the room he got out of bed, fell against an unguarded heated radiator and sustained severe burns on his back, shoulder and side. He sued the defendant university to recover damages for his injuries. The defendant contended that the action could not be maintained against it because it is a charitable institution and the plaintiff, even though a pay patient, was a recipient of its charity. It claimed the fact, which the plaintiff denied, that while the receipts from pay patients were applied toward defraying the expenses of operating the hospital they were insufficient for that purpose and so the deficit had to be met from the income on the university's endowment. To this the plaintiff replied that the action was maintainable, regardless of the claimed charitable nature of the university's activities with respect to the hospital, because the university carried liability, as distinguished from indemnity, insurance whereby the insurer agreed to pay any judgment rendered against the university for negligence. The defendant then filed a rejoinder and admitted that it carried indemnity but not liability insurance and contended that its nonliability was not changed by reason of such insurance. The trial court sustained the plaintiff's demurrer to this rejoinder and rendered a judgment in favor of the plaintiff for \$2,000. From that judgment the university appealed to the court of appeals of Tennessee, middle section.

The general rule, said the court of appeals, is that a charitable institution is not liable for the negligence of its agents and servants, and that rule is not changed if the institution happens to carry liability insurance to protect it against any liability that the law may impose on it. Also, in Tennessee the rule of nonliability extends no further than protection of the trust property of the charitable institution from diversion from the purposes of the charity to the satisfaction of a tort liability. In so holding, the court relied on *McLeod v. St. Thomas Hospital*, 170 Tenn. 423, 95 S. W. 2d 917 (abstr. J. A. M. A. 108:1464 [April 24] 1937), in which the Supreme Court of Tennessee said:

... it fairly may be said that the exemption and protection afforded to a charitable institution is not immunity from suit, not nonliability for a tort, but that the protection actually given is to the trust funds themselves. It is a recognition that such funds cannot be seized upon by execution, nor appropriated to the satisfaction of a tort liability.

If an institution has property other than that devoted directly to the charitable use, such property may be taken to satisfy liability for the negligence of its servants. Accordingly, the university's trust property could not be taken to satisfy a judg-

ment for tort liability, but the liability insurance carried by the university, which was not trust property, could be appropriated for that purpose.

The court did not agree with the defendant's contention that the *McLeod* case, which involved the liability of a charitable hospital for injury to a pay patient's wife, was authority for holding that a charitable institution is liable, out of its liability insurance, for negligence to a stranger but not to a patient. The court took cognizance of the fact that some cases have held that a charitable institution is not liable for negligence to a patient who avails himself of its benefits on the theory that by accepting those benefits he waives any right he might otherwise have to sue for injuries which he may sustain. But, said the court, the waiver theory has not met with approval in this state. Relying on the case of *Gamble v. Vanderbilt University*, 138 Tenn. 616, 200 S. W. 510, L.R.A. 1918C, 875, the court held that the trust theory could not possibly be applicable in the instant case because the plaintiff was delirious and irrational. In his condition he could not justly be held to have agreed to waive a right of action which the law gave him to recover damages for his injuries. From the standpoint of public policy there is as much reason and justice in compensating a patient for injuries sustained as the result of negligence of a charitable institution's servants as there is for compensating a stranger for injuries similarly inflicted. While a charitable institution's trust property is protected from being applied to satisfy a judgment for tort liability, regardless of whether the plaintiff is a patient or a stranger, any liability insurance carried by that institution should be available to a patient as well as to a stranger, where such patient has paid for the services rendered to him. In the judgment of the court the defendant's servants were negligent when they placed the patient on a narrow bed near a hot radiator, knowing that he was delirious and irrational. In the exercise of ordinary care they should have anticipated that he might get out of bed, come in contact with the radiator and sustain the burns which he actually received.

Accordingly, the court of appeals affirmed the judgment of the trial court in favor of the plaintiff and remanded the case with instructions that the judgment be satisfied only out of the defendant's liability insurance. A petition for a writ of certiorari to review this decision was denied by the Supreme Court of Tennessee.—*Vanderbilt University v. Henderson (Tenn.)*, 127 S. W. (2d) 284.

Workmen's Compensation Acts: Reemployment of Injured Workman at Light Work Constitutes Treatment.—If to improve his health an injured workman, on the recommendation of a physician employed by his employer's insurance carrier, is reemployed by his employer at lighter work at the same wages, such reemployment, said the Supreme Court of Kansas, is not a medicine but does constitute "treatment" within the meaning of that term, as it is used in the workmen's compensation act of Kansas.—*Rupp v. Jacobs et al. (Kan.)*, 88 P. (2d) 1102.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Technic for Radiographic Identification of Lesion Seen in Rectosigmoid with Help of Sigmoidoscope. B. S. Epstein and M. J. Matzner, Brooklyn.—p. 179.

Treatment of Amebiasis by Combined Method.—Mateer and his associates reduced the therapeutic failures of the carbarsone treatment of amebiasis from 10 to 3 per cent by combining it with retention enemas of chiniofon. A single course of carbarsone was given in 104 cases of amebiasis, 0.25 Gm. before breakfast and supper for ten days and enemas of 250 cc. of a 2.5 per cent chiniofon. The enemas were given in the knee-chest position, maintained for five minutes and changed for thirty minutes each to the right side, the left side and the prone position. Follow-up stool examinations consisted of a careful warm stool examination by the same experienced parasitologist every week for four weeks, then every month for five months and subsequently every six months for a total period of three years, or longer when possible. The follow-up study of the 104 patients has varied from six months to three and one-half years. After the combined method of treatment amebas were persistently absent from the stools of 97 per cent, or 101, of the 104 patients. There were no unfavorable drug reactions. The three patients exhibiting a recurrence of amebiasis were treated according to the method (vioform-Ciba) of Reed and his associates. The results were as follows:

Oxidation of Sulfanilamide During Therapy.—Fox points out that the detection of methemoglobin in the blood of patients treated with sulfanilamide provides a clue to the possible mechanism of action of the drug. As this pigment is formed from hemoglobin only by the action of strong oxidizing agents, the opinion seems warranted that a rather powerful oxidizing agent is present during treatment. Sulfanilamide is not an oxidant and does not form methemoglobin outside the body. The author presents the following points in support of this hypothesis: 1. Complete, initial deprivation of oxygen interferes with bacteriostasis. 2. Increased oxygen availability magnifies bacteriostasis. 3. Reducing agents and large inoculums, which rapidly reduce the potential, obliterate bacteriostasis despite an excess of sulfanilamide. 4. The use of a preformed oxidant derived from sulfanilamide, 4-hydroxylamino sulfonamide, eliminates the usual initial growth period before bacteriostasis appears and gives a more prolonged effect than sulfanilamide. 5. The occurrence of methemoglobinemia in the course of therapy and the occurrence of an oxidation product of sulfanilamide in the urine of treated patients confirm the view that an oxidant is produced in the blood or tissues of the patient.

Adie's Syndrome.—McKinney and Frocht cite seven cases of Adie's syndrome which simulated tabes dorsalis but were of nonsyphilitic origin. The syndrome is characterized by the tonic pupil and the loss of one or more deep reflexes. These symptoms are chronic and stationary. Typical and atypical types exist. The typical case shows a unilateral tonic pupil and one or more absent deep reflexes. These signs remain stationary, do not otherwise impair the patient's health and tend to occur in younger people, more frequently in women. The typical tonic pupil may be tonic to both light and in accommodation but most frequently is fixed to light, dilates slightly in the dark and reacts tonically in accommodation. The tonic reaction is characterized by the slow response to the stimulus usually with a latent period or delay. The tonic pupil contracts slowly and may eventually become smaller than the normal. When the stimulus is removed it may continue to contract, remain stationary for several seconds or proceed to dilate at once. Dilatation once begun tends to proceed at an even slower rate than the preceding contraction. A typical tonic pupil is subject to sudden variations in size, sometimes concomitantly with emotional stress. An atypical tonic pupil may be bilateral. It may be smaller or of the same size as the affected pupil and may be oval in either the vertical or the horizontal diameter. There may be a tonic pupil on one side and a fixed pupil on the other. Adie includes certain cases of a fixed pupil, iridoplegia or internal ophthalmoplegia in this group. Hippus has frequently been reported in association with the tonic pupil. The loss of deep

reflexes is typically confined to ankle jerks and is most often unilateral. Arm jerks have never been lost by any of his patients, and an absent knee jerk was not observed unless the ankle jerk on the same side was also absent. These patients never show ataxia or sensory changes. Adie's syndrome must be differentiated from Argyll Robertson pupil. Diphtheria occasionally gives rise to an internal ophthalmoplegia but never a tonic pupil. True tonic pupils have never been reported as due to epidemic encephalitis and no case of Adie's syndrome has ever shown any of the early or late symptoms of this disease. The possibility of the tonic phenomenon being related to congenital myotonia, Thomsen's disease, is to be considered. However, the absence of muscular myotonic phenomena, the fact that repetition does not quicken the reaction of the pupil and that quinine has no effect make this association seem unlikely. Not all cases of anisocoria fall into the group of the Adie syndrome. In the absence of demonstrable ocular and nervous system lesions, especially if there is any familial or hereditary incidence and inequality of the pupil is associated with diminished or lost ankle jerks, one is justified in placing the case in this group. The inclusion by Adie of the fixed pupil as an atypical form of this syndrome is confusing, as the fixed pupil is a part of many diseases of the nervous system other than the one Adie describes. The localization of the lesion and its nature are unknown. The authors are inclined to agree with Adie that it is a benign disease *sui generis* and that the syndrome coexists with other diseases but is not caused by them. They encountered their seven cases in the last eighteen months and therefore believe that the disease is not rare but that it is frequently overlooked and that many of the cases are still being treated for syphilis in spite of negative serologic tests.

Capillary and Corneal Osmosis in Glaucoma.—Luedde defines glaucoma as an intra-ocular edema with inadequate drainage. Edema is directly related to osmosis of fluid through the walls of the capillary network. Glaucoma may be caused by general or local conditions which influence capillary permeability or which obstruct drainage from the eyeball. Capillary permeability may be affected by vasomotor disorders related to nervous or chemical stimuli, posture or trauma and also by toxic or nutritional alterations of the blood plasma which may modify the intracapillary colloid osmotic pressure of the blood. Variations in capillary blood pressure are more significant for glaucoma than the general blood pressure. Intracapillary pressure may be relatively low when the general systolic pressure is elevated. Comprehensive treatment of glaucoma may include sympathicotonic remedies for vasomotor control, elimination of focal or general toxins and other medication and regulation suggested by a general examination. Imperfect drainage from the eyeball may be caused by blockade of any normal venous or lymphatic efferent channel. Clinical and experimental studies support the preeminence assigned to the iridocorneal drainage angle, because it leads to the venous plexus in the canal of Schlemm and permits transudation of intra-ocular fluids through the corneal limbus into the subconjunctival spaces and possibly to the external surface of the cornea. Therefore local medical treatment should include ischemics to reduce local congestion and miotics to open the iridocorneal angle. Successful surgical therapy may include the opening of the iridocorneal angle, transfixion or excision of iris tissue and the establishment of sub-

conjunctival drainage through the corneal limbus. Because of corneal permeability, it is probably more important to excise a small portion of corneal stroma than to cut into the sclera to secure a filtering scar at the limbus.

Immunization Against Pneumonia.—Felton arrives at the following conclusions after a study of 1,099 persons before and after immunization with an antigenic pneumococcus polysaccharide, polyvalent types I and II: (a) the percentage of persons with antibody prior to immunization is 32.2 per cent with type I and 32.6 per cent with type II; (b) after immunization, the percentage showing serum antibodies is 94.5 for type I and 98.9 for type II; (c) this response shows no significant variation in the different age groups; (d) irrespective of the age groups tested, the response as indicated by serum antibody titer varies from protection by 0.1 cc. of serum against 100,000 lethal doses to that against as little as 1 lethal dose; (e) certain persons fail to produce antibody—with type I out of 1,099 there were sixty, or 5.5 per cent, and with type II twelve, or 1.1 per cent. It is suggested that this individual variation to pneumococcus polysaccharide antigen is an important factor in the relative resistance to pneumococcal infection.

Extrapleural Pneumothorax.—Dolley and his associates reviewed 141 operations on 135 patients and data on 2,500 cases from clinics abroad and in the United States. Theoretically, an endothoracic extrapleural pocket maintained by air pressure as a substitute for an inadequate intrapleural pneumothorax approaches the ideal. The authors adopted the classification of Schmidt, Adelberger and Theiss, who define indications for extrapleural pneumothorax as absolute, broad or conditional. Extrapleural pneumothorax patients require less postoperative sedation than thoracoplasty patients. Immediately following the

closure of the wound sufficient air is injected into the extrapleural pocket to establish + 10 or + 15 pressure. This usually amounts to from 75 to 125 cc. The needle is inserted just lateral to the incision. Twenty-four hours after the operation air is again introduced. A daily fluoroscopic examination is made for the first week and the patient is given from one to four refills during this period, after which he is placed on a weekly schedule. From four to six weeks after the operation there is a progressive increase in the size of the pocket with a rise in final pressure readings. If the pocket contracts to a point at which it is feared that further expansion of the lung will be accompanied by reopening of the cavity, the patient is placed on a biweekly refill schedule. If this does not control reexpansion, so-called antisymphysial oleothorax of Schmidt is created. Postoperative complications are hemorrhage, infection, emphysema, embolism, atelectasis, tuberculous bronchopneumonia and pleuritis. Intrapleural pneumothorax should be attempted before an extrapleural space is created. When a limited thoracoplasty combined with extrafascial apicolysis affords the probability of cavity closure without an extensive sacrifice of uninvolved lung, it is the procedure of choice. When these conditions do not obtain, the ultimate prognosis for return to economic self support seems fully as good with extrapleural pneumothorax, despite the protracted requirements of space maintenance. In the conditional group of thirty-five patients 40 per cent have negative sputum, 49 per cent have positive sputum and 11 per cent are dead. Of forty patients in the broad group 70 per cent have negative sputum, 27 per cent have positive sputum and 2 per cent are dead. Of the twenty-five patients with absolute indications, all have negative sputum. No death has occurred. The results convince the authors that the creation and maintenance of an extrapleural pocket is the most satisfactory procedure when the indications for it are either absolute or broad, when the patient refuses thoracoplasty and is very young or old, when thoracoplasty would reduce vital capacity so much that anoxemia would preclude future physical activity, when bilateral disease precludes thoracoplasty, when frequent alarming hemorrhages render graded thoracoplasty a hazardous undertaking and when there is serious constitutional disease. The conclusions of the men who furnished data on the 2,500 cases are: 1. Intrapleural pneumothorax and limited thoracoplasty are to be preferred when they can be reasonably relied on to produce cavity closure and sputum conversion. 2. When neither is likely to succeed, extrapleural pneumothorax will be instrumental in obtaining approximately 63 per cent of sputum conversions. 3. Comparatively early oil conversion is advisable to control the pocket, to eliminate the difficult space maintenance, to reduce expense of frequent refills and to minimize infection. 4. The end result will be permanent oleothorax or partial lung reexpansion with a small residual oleothorax or obliterating extrapleural fibrosis with little likelihood that a thoracoplasty will be required.

Vitamin C in Tuberculosis.—Chang and Lan studied the vitamin C content of the blood and urine of 100 tuberculous patients and of ten normal persons. The saturation test was also carried out to see whether hypovitaminosis C in tuberculosis indicates an original unsaturation of the vitamin in the body. In tuberculous patients the range of vitamin C in blood plasma was from 0.03 to 0.6 mg. per hundred cubic centimeters, while in normal persons it was from 0.64 to 1.14 mg. The amount of vitamin C excreted in the urine in twenty-four hours by the tuberculous patients ranged from 1.3 to 69.54 mg., while in normal persons the range was from 24.4 to 72.6 mg. The tuberculous patients who excreted comparatively large amounts of vitamin C in the urine showed a low concentration in the blood plasma. This may indicate a lower renal threshold for vitamin C in tuberculous patients. In many other cases there was a low vitamin C level in both blood and urine; this may again point to "unsaturation" of the vitamin in the body tissues. Analysis shows that the more severe the tuberculous infection the lower the figure: in tuberculous patients with unilateral pulmonary tuberculosis the vitamin C plasma content was 0.373 mg. and the urinary excretion 28.109 mg., while in bilateral pulmonary tuberculosis the respective figures were 0.227 and 20.546 mg. In the childhood type of pulmonary tuberculosis the vitamin C content in the blood was found to be higher than in the adult type, while the quantity of vitamin C eliminated in the urine was much less than in the adult type. This may be

because children excrete comparatively smaller amounts of urine and hence the vitamin C contained in it is less than that in the adult urine. The saturation test performed on five tuberculous patients and two normal persons indicated that the vitamin C in the body is proportional to the severity of the tuberculous infection.

Cervical Ribs and Scalenus Muscle Syndrome.—Patterson reports thirty-one cases of cervical rib which fall into four groups: (1) enlarged transverse process, usually of the seventh cervical vertebra, (2) bilateral ribs of the floating type or articulating with the first rib, (3) unilateral rib, either floating or articulating with the first rib and (4) rudimentary rib tip, either single or bilateral. One patient had rudimentary rib tip at the sixth cervical vertebra and fully developed ribs from the seventh cervical vertebra. A single rib, with or without a rudimentary tip on the opposite side, was three times as frequent as bilateral ribs. Enlarged transverse processes and bilateral ribs were about equal in number. The symptoms of sixteen patients related to pressure or irritation of some part of the brachial plexus or subclavian artery. The lower nerves of the brachial plexus were more commonly involved. The patients' complaints, in their relative frequency, were pain of varying intensity, tiredness and weakness of the extremity, cramps in the fingers, numbness, tingling or coldness of the hand, areas of hyperesthesia, shrinking of some of the muscles of the hand, a lump at the base of the neck, tremor of the fingers and discoloration of the fingers. Work and exercise accentuated the symptoms. They were in part relieved by elevation of the upper extremity and by rest. For operative approach the author advises division of the anterior and medial scalenus muscles and removal of the rib. Division of the anterior scalenus through the muscle belly helps to avoid injury to the pleura. The dome of the pleura is probably higher in the neck of people with cervical ribs. Even in the presence of a cervical rib, differential diagnosis must exclude arthritis of the spine or shoulder, bursitis, apical tumors, neuritis, vascular diseases, congenital deformities and cardiac disease. Lateral roentgenograms will frequently show the cervical rib running diagonally across the body of the seventh cervical vertebra; they will also show the pleura at the base of the neck in front of the spine. Aneurysms of the subclavian artery caused by cervical ribs or anterior scalenus syndrome are rare. If present they may be doubly ligated and resected with safety. Circulatory disturbances are probably due to repeated stimulation of the vasoconstrictor nerves or to direct pressure on or angulation of the subclavian vessels.

Duodenojejunoscopy for Atresia.—Stetten operated successfully in a congenital case of intrinsic total atresia at the duodenojejunal junction. A boy baby 3 days old and one month premature did not retain any feedings, vomited bile-stained material from birth and had passed only a few meconium stools. He was feeble, emaciated, deeply jaundiced and quite dehydrated, weighing 4 pounds 2 ounces (1,871 Gm.). The abdomen was distended, the stomach dilated with visible gastric peristalsis, and an indefinite sausage-like mass could be palpated running

obliquely from the right upper to the left lower quadrant. X-ray examination showed no passage of barium after three and one half hours beyond the point of obstruction at the duodenojejunal junction. At operation, under ether-drop anesthesia, the sausage shaped duodenum was yellowish pink and occupied a good part of the abdomen. The distended duodenum terminated abruptly, closed by a total, intrinsic diaphragmatic atresia, and continued in a much contracted, thin-walled jejunum which was not much more than 0.125 inch in diameter. The remainder of the small and large intestine was crowded over to the left side of the abdomen, and the ileocecal junction, a tiny appendix and a primitive cecum lay in the angle formed by the stomach joining the duodenum—indicating an arrested rotation of the colon. The lumen was patent and a typical lateral, quite satisfactory antiperistaltic duodenojejunosomy, about 0.72 inch in length, was made. The child was kept in the incubator for five weeks. Blood transfusions were given and clyses, twice daily, were continued until the diarrhea was controlled. From then on the recovery was uneventful, with a gradual increase in weight until the child's discharge from the hospital at the age of 3 months, when its weight was 7 pounds 2 ounces (3,232 Gm.). The child is now 22 months old, unusually husky, in excellent health, and has a perfect digestion with normal stools. His weight is 28 pounds (12.7 Kg.) and his height 33 inches (84 cm.).

Ulceroglandular Tularemia.—Terry and Reichle state that of the twenty-three persons in Cleveland who had tularemia during the winter of 1937-1938 (November-March, the period during which rabbits are hunted or shipped in from other places) three died. The three fatal cases were traced to the dressing of wild rabbits. The incubation period was from two and a half to three and a half days in one instance, five days in another and indeterminate in the third. The striking clinical characteristic of the primary lesions was their relatively benign appearance as contrasted with their painfulness. The duration of illness of two patients was six days, while the other died on the tenth day. The clinical course was characterized by hyperpyrexia, severe toxicity, delirium and coma. Icterus was present terminally in one case, while in another bleeding into the skin, subcutaneous tissues, regional lymph nodes and recti abdominis was observed. The serologic observations were fairly constant and characteristic in all cases. Treatment by sulfanilamide (one case), specific immune serum and convalescent serum was not effective. *Pasteurella tularensis* was not found in the circulating blood but was recovered at necropsy from lymph nodes in two cases and from the hemorrhagic mass in the rectus muscles

in the third. Bacterial stains failed to reveal the organisms in tissue sections. The lesions in lymph nodes, spleen, liver and lungs were characteristically those of a necrotizing inflammation in which large mononuclear cells, often actively phagocytic, predominated. Lesions of the gastrointestinal tract were confined to the gastric mucosa, where small superficial ulcerations had resulted in gross hemorrhage. A focal infiltration of lymphocytes and large mononuclears at the base of an ulcer in one case is suggestive but not conclusive evidence of the specificity of the lesion. Microscopic study of the hemorrhagic mass in the rectus muscle revealed no lesions of a specific nature. Cultures from it yielded *Pasteurella tularensis*.

Treatment of Compound Fractures.—Orr's suggestions, first advocated twenty years ago, include rules for early reduction and the application of closed plaster of paris casts. For first aid on the battlefield or at the scene of the accident the use of a tourniquet and traction immobilization in a Thomas splint are life saving and limb saving. The patient thus managed may be transported safely to a hospital where efficient traction, débridement, petrolatum pack drainage and fixation in a cast may be done. The author has followed this plan for years. Trueta employed it successfully during the Spanish Civil War. In the experience of other competent observers good results are obtained by the method of infrequent dressing in from 85 to 90 per cent of compound infected fractures. The same technic is applicable during the first few hours as well as in cases presenting a fracture in malposition, an infected wound, septicemia or pyemia. A restless patient with an unreduced fracture, muscle spasm, pain and a septic wound can do himself more harm every hour than the surgeon in thirty minutes while permanently immobilizing the fractured limb, adequately draining the wound and fully protecting the wound and the limb against further trauma and infection.

Compound Fracture Therapy.—According to Hermann, 398 patients aged from 1 to 80 years with "open," or compound fractures were treated at the bone and joint service of the Boston City Hospital. Treatment began on the accident floor. The treatment consists of immediate institution of shock and

hemorrhage therapy, exposure of the compound fracture, material culture from the wound and immediate covering with a sterile dressing. A prophylactic dose of 100 cc. of gas gangrene antitoxin and 1,500 units of antitetanus serum are given intramuscularly. Patients with large macerated or extremely dirty wounds are given 100 cc. of gas gangrene antitoxin and 5,000 units of antitetanus serum; this dose is repeated twice during the first ten days. The skin round the wounded area is cleansed and shaved and the wound covered with sterile gauze. The wound is debrided and flushed with warm salt solution followed by an ether wash, the bone and its coverings being avoided. The fractured ends are gently curetted and the wound is again gently irrigated. Loose and comminuted fragments of bone should not be removed unless they are practically extruded from the wound and completely separated from all blood supply. X-ray examination often determines the decision between internal fixation and conservative treatment. A small percentage only requires internal fixation. Accurate reduction and apposition are paramount. Whether the wound should be left open, or treated by the Orr method, by dakinization, by primary suture and temporary direct or dependent drainage or by simple primary suture is controversial. They are all good methods. The surgeon should use the method with which he has obtained the best results, but he should not be dogmatic in its use. Hermann and his associates prefer primary closure without drainage. They have used it in 85 per cent of their cases and the Orr method and dakinization in the remainder. The open method was employed when a large area was involved. A large percentage of patients without internal fixation and in whom the fracture has been more or less easily reduced do well with the molded plaster of paris cast. Fractures with a marked degree of overriding or comminution with displacement require traction in arm or leg splints. Complicating gas bacillus or tetanus infection should receive prompt and radical treatment with appropriate stimulation and supportive medical measures. The same may be said of the virulent streptococcal and staphylococcal infections. The original culture of material taken from the wound may give an even earlier warning than the characteristic odor of gas infection.

Situs Inversus and Biliary Tract Disease.—According to Wood and Blalock, the literature reveals only seventeen cases of lesions of the biliary tract associated with situs inversus. In several of these the diagnosis has not been confirmed by x-ray or operative examination. Only one of the nine patients giving this information was left handed. In eleven of the sixteen cases in which the location of pain and tenderness was mentioned, the left upper quadrant of the abdomen and the back were the major points of involvement. In two instances most of the discomfort was on the right side, and in three it was in the epigastrium. The tendency of pain to be referred to the right from a viscus transposed to the left is not so great with cholecystitis as it is with appendicitis. In more than half of the cases of appendicitis associated with situs inversus the localizing signs were in the right lower quadrant of the abdomen. The authors' case is one of only two presenting disease of the gallbladder and situs inversus in which most of the discomfort was in the right upper quadrant. These facts make the anatomic and pathologic diagnosis of "left sided" cholecystitis somewhat easier than that of "left sided" appendicitis. Although situs inversus is usually compatible with normal health and longevity, there is some evidence that persons with this condition have a higher percentage of congenital abnormalities. The incidence of bronchiectasis in situs inversus is markedly increased. The status of situs inversus has changed from that of an anatomic curiosity to a clinically important entity. Its early recognition is especially important in certain surgical emergencies.

Diabetic Coma.—Fowler and his associates record a series of blood sugar time curves to demonstrate the different responses to treatment of diabetic coma with one simultaneous injection of 100 units of unmodified insulin intravenously and 100 units of unmodified insulin and 200 units of protamine zinc insulin subcutaneously. All the cases demonstrated that there need be no fear of hypoglycemic reactions when the treatment is combined with frequent feedings of carbohydrates. A table recording the carbohydrate balances of eleven cases demonstrated that the average blood sugar before treatment of 0.612 per cent was reduced to 0.165 per cent during an average period of 5.5 hours, and that, despite the administration of an average of 781.4 Gm. of sugar during a period of 34.4 hours, the average amount found in the urine was 52.4 Gm. only; that is, an average of 729.0 Gm. was retained. This retention was not artificial but due to utilization either by storage or by oxidation. These patients utilized not only the enormous amounts of carbohydrates administered but also, either by storage or by oxidation, appreciable amounts of the excesses which the blood contained prior to treatment. Correlation of clinical and laboratory data and comparison with the old method of treatment have shown that recovery is more rapid with the new method and convalescence more satisfactory. The mortality with this method of treatment is definitely less than with the older methods.

Antenatal Tuberculosis.—Moss and Stoesser report a case of prenatal tuberculosis with no postnatal exposure to the disease. Study of the case suggests that the antenatal tuberculosis arose from aspiration of infected amniotic fluid, as the involvement at necropsy of the 38 day old infant was most marked in the respiratory tract. Neither the placenta nor the amniotic fluid was available for examination, as the condition was not suspected until the baby was studied at necropsy. The infant was not in contact with the tuberculous mother. It was transferred to the pediatric service immediately after birth. The child's condition remained fairly good for twenty-eight days, at which time the temperature rose to 102 F. and from that time the temperature rose daily to 103 F., rising to 105 F. on the

day of death. There were intractable diarrhea and spells of cyanosis and persistent hyperpnea. Repeated examinations revealed no definite cause for the respiratory and intestinal distress; the clinical picture resembled pneumonia. At necropsy most of the organs were normal except the lungs and thymus, in both of which firm yellowish nodules were found. On pressure, thick creamy material was expressed from the nodules about and in the thymus. Microscopic examination revealed numerous polymorphonuclear cells and large necrotic mononuclear cells in the bronchi and alveoli. The necrotic material did not appear caseous, and in many areas the epithelioid cells had oriented themselves in a circumferential direction to give a surrounding thin zone resembling a zone of fibrosis. Smears showed numerous acid-fast bacilli. A few small atypical tubercles were seen in the liver. These showed central necrosis which did not appear caseous. A few areas in the spleen contained more or less atypical tubercles. Multiple tubercles were observed in the thymus and lymph nodes. Large and small lymphocytes were present in the sinuses. Several well circumscribed cortical adenomas were present in one adrenal and an extracapsular hemorrhage in the other adrenal. Immediately following delivery the mother (aged 33) began to have a fever of from 100 to 102 F. The Mantoux test on admission was strongly positive. X-ray examination eight days after delivery showed no evidence of pulmonary pathologic changes. After the necropsy of the infant a biopsy of the mother's cervix was performed and the lower uterine segment curetted. The pathologist reported a tuberculous involvement of the endometrium and cervix. X-ray studies of the chest indicated a possible capillary bronchiolitis. It was questionable whether the changes in the chest could be due to miliary tuberculosis. During her hospital stay of sixty-five days catheterized urine was repeatedly negative. Repeated sputum and stool examinations were negative for tubercle bacilli. Further x-ray examinations revealed that the pulmonary process was miliary tuberculosis. Death occurred from generalized miliary tuberculosis four months post partum. Necropsy revealed the presence of nodular pulmonary tuberculosis, generalized miliary tuberculosis, tuberculosis of the peritoneum, endometrium and cervix, appendical abscess with communication into the cecum and tuberculosis of the right uterine tube.

Tuberculin Testing of College Students.—Cox and Thornton discuss the results of four years of tuberculin testing in six colleges with a total enrolment of 8,676 students. Of these only 4,417 were accessible for the tuberculin test, 3,421 or 77.5 per cent of whom responded. There were 23.6 per cent positive tuberculin reactors. The positive reactions were higher in students coming from urban areas. The majority of students (75 per cent), lived in sparsely settled communities. There was an increasing incidence of tuberculous infection from the first to the fourth year in college, the average increase being 1.2 per cent annually. A history of contact was given by 23.3 per cent of the group and positive reactions were twice as prevalent in these cases. There was a high incidence of tuberculous infection when the contacts had close relationships or associations.

Fluorography.—Cestero defines fluorography as a combination of the processes of a camera, a fluorescent screen and an x-ray tube. The result is a minute photograph which, when flung on a screen or looked at through a magnifying glass, is augmented to twice or six times its diameter without loss of the smallest detail of diagnostic value. As a result of the improvement of the modern x-ray apparatus, the technic of fluorography is practically perfect. Modern photographic lenses have an extraordinary speed. During the last three years, emulsions used in photographic work have produced almost incredible results. Some are actually sensitive to infra-red. The fluorograph constructed by the author is 12 inches wide, 16 inches high and 33 inches long. He uses a Patterson B 12 by 16 inch fluoroscopic screen, and a Leica f/2 lens. The focal spot screen distance is 25 inches and screen film distance is 33 inches. The object was to use each film (2.4 by 3.5 cm.) to its fullest extent. The sensitive surface of these films is less than 200 times smaller than the usual film and their cost is 100 times less. Before the introduction of the paper film the cost of each chest film per capita was \$1. In a smaller number of fluorographic tests the per capita cost was shown to be 3 cents. This short test shows

that fluorography is forty times more economical than fluoroscopy and roentgenography. However, the method does not pretend to supersede either. The method has the advantages of low cost and accuracy of detail, necessary when dealing with mass tuberculosis surveys. It is the only means so far developed by which a thoracic census can be made in Puerto Rico rapidly, economically and efficiently.

The Biophotometer Test and Vitamin A Content.—Baum and McCoord state that of ninety-eight untrained children tested once with the biophotometer nineteen showed subnormal dark adaptation by Jeans's standards. The more lenient Frober-Faybor standards showed the same normal grouping, but only one subject had a subnormal reading. Seventy children whose dietary history was obtained showed no correlation between their diets and the biophotometer readings. Subjective symptoms of vitamin A deficiency were not complained of. Correlation was absent between all readings of the biophotometer and the vitamin A, carotene and xanthophyll content of the blood. The vitamin A content of the blood agreed well with the clinical condition of the patient and has shown the expected variations after vitamin A absorption tests. It may be that a single estimation may not give the correct estimation of the supply of vitamin A to the retina. Several of nineteen trained subjects showed improvement on repeated testing without administration of vitamin A. Although about 20 per cent of the untrained subjects were classed as subnormal by Jeans's standards, only about 10 per cent of the trained ones fell in the subnormal range. Biophotometer readings in this group showed no correlation with blood vitamin A values, but there was a suggestive correlation between the *d*, or first reading of the second test period, and the average carotene content of the blood. This may be of

interest in view of Wald's observations that carotene improves dark adaptation in a deficient subject more rapidly than does vitamin A.

Vitamin D in Rickets and Tetany.—According to Vollmer, parenteral administration of one massive dose of vitamin D in a solvent of peanut oil and ether had the same effect on rickets and tetany of 158 infants and acted as quickly as the same doses of vitamin D administered by mouth. Serum calcium and phosphorus became normal after from three to seven days. Generally the calcium deposition in the bones made its first x-ray appearance in one week, proceeded rapidly and was usually complete thirty days after treatment was begun. Tetanic convulsions ceased within twenty-four hours after the parenteral administration of the one massive dose of vitamin D. No difference was observed between the effect of vitamin D₂ and vitamin D₃. The parenteral administration of 600,000 units of vitamin D caused no local infiltration or evidence of systemic damage. No casts containing calcium were found in the urine.

Influenzal Meningitis.—Silverthorne and his associates made a comparative study of influenzal meningitis over a period of twenty years. Of seventy patients treated from 1919 to 1929 sixty-nine died, a mortality of 98 per cent. From 1930 to 1939 sixty-five patients were treated with anti-influenzal serums and fifty of these died, a mortality of 76 per cent. "Head colds" occurring from two days to one month prior to the onset of meningeal signs were present in thirty-one of the sixty-five. Fever, vomiting, drowsiness and irritability were present in the majority. "Soreness of the neck" or "stiffness of the neck" on attempted movement was complained of by many children. There was little difference in the mortality of patients treated with anti-influenzal horse serum intravenously and anti-influenzal horse serum and human serum (complement) intrathecally and of those treated with anti-influenzal horse serum intravenously and bactericidal guinea pig serum intrathecally. During the last four years the authors studied thirty-two cerebrospinal fluid strains of *Haemophilus influenzae* from their patients. Thirty-one of the strains examined fall into type B. Twenty-eight of the thirty-two strains were found to have some degree of virulence and four strains showed no virulence in mice. From the observations it appears that cerebrospinal fluid strains from cases of influenzal meningitis are, in the main, a homogeneous series, with a few exceptions: One strain did not produce indole, one strain was not type B, and four strains (three patients from whom these strains were obtained recovered) did not possess virulence when injected with mucin into mice intraperitoneally. Because of technical difficulties in the production of guinea pig serum, the authors developed an immune anti-influenzal rabbit serum which contains mouse-protecting antibodies against a fatal infection with meningeal strains of *Haemophilus influenzae*. They used this serum and sulfapyridine in one case, with gratifying results. Chemotherapeutic agents with immune serum mixtures are recommended rather than the use of either alone. In addition, continuous intravenous therapy and daily lumbar puncture with drainage should be carried out. In a series of experiments they found that, with the combined therapy, mouse-protecting antibodies are developed in the serum of rabbits injected with meningeal strains of *Haemophilus influenzae*.

Laryngeal Tuberculosis.—Looper found the onset to be most frequent between 20 and 40 years of age in a study of 500 patients with laryngeal tuberculosis. The complication is secondary to the pulmonary condition and results from lowered tissue resistance. The diagnosis is not difficult and the lesion responds to treatment. The classic subjective symptoms should not be waited for before the larynx is examined. The posterior laryngeal wall is the most frequent as well as the first area to be infected. The anatomic construction of the interarytenoid region makes it particularly susceptible to invasion of tubercle bacilli. Next in order of frequency are the vocal processes and the vocal cords. The ventricular bands are not involved as frequently as the cords, but a lesion here may be very extensive, and tuberculomas are not uncommon. The prognosis here is much better than in disorders of the arytenoids, epiglottis or pharynx. Pharyngeal tuberculosis is fortunately rare. It is a grave condition for which little can be done. Certain complaints often help to recognize early lesions. Dryness and burning of the throat should be regarded with suspicion. This frequently occurs two or three weeks before a definite lesion can be seen. Pain referred to the ear and in the region of the throat usually indicates some laryngeal infiltration. A well advanced infection in the interarytenoid space or ventricle may give little or no disturbance, but a small degree of infiltration of the cord will produce huskiness and later hoarseness or aphonia. Infiltration and ulceration around the arytenoids and epiglottis interfere with swallowing. A biopsy may be necessary. Many cases of laryngeal tuberculosis can be prevented by earlier recognition, educational measures and correction of pathologic conditions in the upper respiratory tract. In all cases in which tuberculous invasion of the larynx has been discovered, absolute rest of the voice is essential. The electric cautery has been most beneficial. Early lesions clear up after two or three treatments, and advanced cases show marked improvement after a few cauterizations. The cautery is of great palliative value in severe and hopeless cases. Of the 500 patients with laryngeal tuberculosis treated in the sanatorium, 142 had moderate pulmonary involvement. The throats of ninety-five were cauterized. The throats of 136 of the 358 patients with far advanced pulmonary involvement were cauterized. The throats of ninety-three patients of the first group were improved and healed, and two patients died.

The laryngeal lesion in both of these had healed. Of the patients in this group whose throats were not cauterized, fifteen were improved and healed, twenty-six were unimproved and six died. Of the 136 patients in the second group, cautery treatment improved and healed the throats of ninety-three, twenty-two were not improved and nineteen died. Of the 222 patients in this group whose throats were not cauterized, fourteen were improved and healed under sanatorium care, 112 were unimproved and ninety-six died. Cautery treatment is contraindicated in advanced toxic cases.

Chronic Brucellosis.—According to Dustin and Weyler, the clinical picture and course of the usual acute form of brucellosis has been adequately described; they believe, however, that there exists a chronic form of this infection in human beings. A study of more than 4,000 individuals in Rhode Island during the past four and a half years has revealed in 441, or about 10 per cent, clinical and laboratory evidence supporting a diagnosis of chronic brucellosis. Seven hundred and ninety-nine (18 per cent) had positive reactions to one of the following three tests: intradermal, intramuscular, agglutination. The 441 who had clinical evidence of chronic brucellosis showed positive reactions to at least two of these. The relation between chronic brucellosis and personal allergy is significant. In 92 per cent of the cases studied there was a history of allergy and in all there was a history of allergy in the immediate families. Many so-called neurasthenics may be suffering from this condition. Its clinical aspect is varied and puzzling to the patient and physician alike. It does not follow the usual course of chronic infection so much as it does that of a chronic allergic state. If chronic brucellosis is considered from the standpoint of allergy, desensitization would be a reasonable system of treatment. Because of the unusual characteristics of the brucella organisms and the ease with which all food produce, including meats, eggs, butter, ice cream, cheese, milk, fruits and vegetables, may become contaminated, it is evident that milk should not be regarded as the commonest source of infection. The authors describe their application of the available diagnostic methods and enter a plea for more serious consideration of chronic brucellosis.

Changing Factors in Diphtheria Immunity.—According to Stebbins and his collaborators, an analysis of mortality from diphtheria in New York State from 1898 to 1937 indicates that some factor tending to reduce mortality has been in operation since 1900 but that the rapid acceleration in the decrease in mortality in recent years coincides with the increase in artificial immunization. An attempt was made to determine the comparative efficacy of the three different immunizing agents used extensively in the state in terms of immunity as measured by Schick test surveys and by the incidence of clinical diphtheria among the groups of individuals given immunizing treatments. The gross results of treatment with the different agents, measured by Schick tests in two cities in 1938, seem to indicate no difference in the efficacy of toxin antitoxin and alum precipitated toxoid but significantly inferior results following fluid toxoid. The incidence of clinical diphtheria in individuals immunized with the different agents was compared, but, because of the probable difference in risk of exposure, conclusions as to the efficacy of the agents drawn from these data would be of questionable validity. Observations on the prevalence of diphtheria carriers in two cities, Kingston and Ossining, in which the incidence of clinical diphtheria has been extremely low for several years, showed a distinctly lower prevalence of both avirulent and virulent carriers than has been reported from carrier surveys in areas in which clinical diphtheria was more prevalent. In Ossining a slight but significant increase in diphtheria occurred immediately preceding the survey and, while the prevalence of carriers of *Corynebacterium diphtheriae* was not increased, the prevalence of toxigenic organisms was higher than in Kingston, where clinical infection continued at a low level. These observations suggest a direct relationship between the prevalence of clinical infection and the prevalence of carriers of virulent organisms. In view of the present decreased prevalence of carriers of toxigenic *Corynebacterium diphtheriae* in Kingston, the rapidity of natural immunization might be less than at a time when clinical infection occurred more frequently. The proportion of Schick-negative reactors in the age groups observed in Kingston in 1922 compared with the results among persons not artificially immunized who were tested in the 1938 survey, while showing no difference in the proportion of Schick-negative individuals of all ages, did show a significantly lower proportion of negative reactors in children under 10 years of age in 1938. These observations lend support to the theory that with the decreasing incidence of clinical infection and the associated decrease in the prevalence of carriers of toxigenic *Corynebacterium diphtheriae*, natural immunization is materially reduced.

Acute Infectious Lesions of Intervertebral Disks.—Ghormley and his colleagues discuss the occurrence of a lesion of the spine which involves principally the intervertebral disks. There is a more or less severe febrile onset, denoting a primary or secondary infectious process as the underlying cause. In the American and English literature the cases are referred to as osteomyelitis of the vertebrae. The authors have observed several cases in which x-ray evidence of actual osteomyelitis was so slight as to furnish a reasonable doubt. Sternberg described similar cases under the name of "acute spondylitis infectiosa" and drew a clearcut picture of the difference between osteomyelitis of the spine and the condition under discussion. Infectious spondylitis usually follows typhoid or paratyphoid (typhoid spine) and may occur as a sequela to other infectious diseases, such as undulant fever. A definite knowledge of this condition exists, but no attempt has been made to distinguish it from osteomyelitis of the vertebrae. Twenty patients with infectious spondylitis have been seen at the Mayo Clinic. Fifteen were male and five female. The average age was 34.1 years, the youngest being 9 years and the oldest 59. The average duration of the acute symptoms was 21.6 weeks, the shortest six weeks and the longest two years. Twelve patients had a history of previous infections. In some the onset seemed to follow a mildly severe backache for from one to two weeks. A stage

was then reached in which the patient was severely ill. All the patients complained of pain. Fever was present at the time of onset in sixteen. There was a spasm of the lumbar or psoas muscles or both in eighteen, limitation of motion in seventeen and tenderness over the affected region in seventeen. Roentgenograms during the acute phase are usually normal, but when carefully followed a diminution in the thickness of one of the intervertebral disks appears. Followed over a period of months, increased thinning of the space and later proliferation of new bone along the margins of the involved vertebrae are observed. Finally solid bony fusion may be observed. In the earlier stages there may be some thickening of the paravertebral soft parts. This is not constant. If extensive vertebral involvement is present a diagnosis of osteomyelitis of the spine should be made, but when only the disk and the adjacent portion of the vertebral body are involved the condition is not true osteomyelitis. In the more advanced cases with obvious thinning of the disk in the roentgenogram the differential diagnosis is narrowed down to tuberculosis, post-traumatic thinning of the disks, typhoid spine, *Brucella abortus* or *melitensis* and congenital absence of disks or fusion. A diagnosis of tuberculosis is justified when the onset is slow and insidious with mild symptoms associated with tuberculosis of some other organ. In infectious spondylitis the onset is often more violent or it is preceded by some acute infectious process elsewhere and leads to a much more rapid and spontaneous healing, with fusion of the adjacent vertebrae as the usual end result. Osteomyelitis of the vertebrae in the more advanced stage presents a much more serious and prolonged disease than infectious spondylitis. Typhoid spine is almost if not exactly identical. *Brucella abortus* or *melitensis*, congenital absence of disks or fusion of vertebrae is usually readily recognized. The prognosis is excellent, both as to ultimate recovery with little or no disability and as to mortality. Only one of the authors' patients died. Two of the twenty patients have persistent symptoms. Two have not had any recent follow-up. Patients with fever, prostration and extreme pain must be treated symptomatically, sedatives being used until the diagnosis is established when a snugly fitted plaster of paris body cast on a Goldthwait frame is used to fix the spine during the acute phase of the disease. Pain will usually subside and after two or three months sufficient healing will have taken place to permit the use of a steel brace or a corset. Such support must be continued until the symptoms have cleared up, perhaps for a year or more. In cases of persistent pain, fusion has been advised but done in only one case.

Differential Diagnosis of Breast Tumors.—Scott points out that any cancerous involvement of the interlobular fascia, to which Cooper's ligaments are attached, may restrict the ligaments and skin when the tumor is moved in a position to make these fascial tissues tense; and the slightest pull or traction on them will produce depressions in the skin, shown by significant shadows when properly demonstrated. When a malignant tumor of the breast is slowly moved in certain positions until the submammary fascia is made tense the interlobular fascia also becomes tense, and through Cooper's ligaments the overlying skin is restricted in its movements. This restriction sometimes produces deep dimples and at other times shallow depressions, which if examined in direct light may go unobserved. In a darkened room, when rays of light strike a smooth surface at a perfect tangent depressions less than 0.3 mm. in depth will be shown. For many years diagnosticians have considered cutaneous adhesions and deep depressions or dimples as valuable and rather positive signs of cancer. Skin frankly adhered to a tumor and large depressions or dimples readily seen in a bright light falling directly on the breast while in repose are late signs of cancer and are of little if any more value for early diagnosis than the retracted nipple, palpable axillary nodes and definite adhesions to the deep fascia beneath the breast. Breast examinations should be made in upright and prone positions. While the cancer shadow test is being made the room should be darkened and the breast to be examined gently elevated while the tumor is manipulated into various positions. With each change of position, the spotlight (a pencil type) is slowly raised and lowered. When a feeling of tension is detected by the examining fingers, if a malignant growth is present the cutaneous depressions or flattened areas appear. They become quite

visible as the glancing light casts irregular shadows in proportion to the size and depth of the depressions. These depressions are magnified by shadows in the same manner as the uneven surfaces of a highway are made visible and magnified at night by shadows cast from the glancing lights of an automobile. Although cutaneous depressions as observed by magnified shadows are present in a high percentage of malignant breast tumors, they may be misleading when located within the areola or near its borders, as a short lacteal duct or a benign tumor of a duct may cast definite shadows with or without manipulation. Also surface depressions resembling cancer depressions may be observed in breasts which have been the site of a previous inflammatory process, severe trauma or an incisional scar. The shadow test has given the author negative results in so many benign tumors of the breast and positive assurance in so many early malignant cases that he has avoided biopsies in many instances that would have been considered absolutely necessary before simple mastectomy or radical amputation was carried out. The cancer shadow test is most significant as an early diagnostic aid and in his hands has reached a high degree of proficiency. Of 207 breast tumors ninety-nine were diagnosed as cancer and 108 as benign lesions prior to operation. Of the ninety-nine diagnosed as malignant ninety-one, as proved by microscopic examination, were correctly diagnosed. In the group of 108 diagnoses of benign lesions, ninety-eight were correctly diagnosed.

Electrocardiograms in Pellagra.—Mainzer and Krause made electrocardiograms of twenty-three (fifteen men and eight women) pellagra patients. In twenty-one of these the disease was chronic and in two acute. Nine of the patients were more than 50 years of age. This is of some significance as the possibility of cardiographic changes due to coronary sclerosis increases with advancing age, even without clinical symptoms. Patients with clinical circulatory symptoms were excluded from investigation. The electrocardiograms were taken immediately after the patient's admission to the hospital; records of eleven additional patients were taken once or more during their stay in the hospital. Among the abnormalities observed, the most frequent was sinus tachycardia, which occurred in about one third. Alteration of the ST interval and of the T wave were present in the thirteen pathologic records. The records of the other ten were normal. In six of the abnormal records there was deformation of the ventricular complex (low voltage or notching). The observations show no features characteristic of pellagra. However, two clinical arguments favor the assumption that the disturbances have some causal relationship with pellagra. The first is the high incidence of pathologic electrocardiograms in pellagrins with an otherwise normal circulation. This holds true even when it is remembered that in older persons such changes may result from coronary sclerosis without clinical symptoms and that half of the patients with a pathologic electrocardiogram were more than 50 years of age. An abnormal electrocardiogram of one pellagrous woman of 23 was obtained. This patient subsequently died of the disease. The second and decisive proof is furnished by the fact that the pathologic electrocardiogram returned to normal with cure of the pellagra or paralleled the improvement of the disease. Such an occurrence could scarcely be expected if the changes were due to coronary sclerosis (apart from the occurrence of acute infarction). Other irreversible heart disorders that might have induced the electrocardiographic symptoms were ruled out by clinical observations. Shortening of the conduction time which is rather characteristic of beriberi in the cardiograms of some pellagrins justifies the assumption that, similarly to the peripheral neuritis in pellagra, this symptom is brought about by the deficiency in vitamin B₁.

Prevention of Mastoiditis.—Horan and French review 621 cases of suppurative otitis media treated with sulfanilamide. The patients were given an emulsion of sulfanilamide by mouth in full doses according to age and weight. Medication was continued to a total dose of 40 Gm. Often the ear recovered before the maximal dose had been reached. Parenteral administration of azosulfamide was resorted to when it was thought advisable to reach the maximal concentration in the minimal time. Sulfapyridine was substituted for sulfanilamide if pneumococci were isolated. Many patients were treated as outpatients under constant supervision. No serious toxic manifestations were seen. The incidence of mastoiditis was only 3.4 per cent, compared with 22.7 per cent before the introduction of sulfanilamide therapy. The authors urge that all patients with acute suppurative otitis media be given sulfanilamide or sulfapyridine, because this will greatly reduce the incidence of mastoiditis and will allow a more conservative attitude to be adopted once mastoiditis develops.

Causes of Failure of Nerve Sutures.—Leriche believes that nerve suture fails in many instances because of excessive shortening of the nerve. He stresses the necessity of preserving local circulation. Efforts must be made to prevent muscle atrophy, bone rarefaction, deformity of joints and contracture of ligaments. Sutures that are on tension are inadvisable. When the distance to span is considerable, better results will be obtained by the use of a nerve graft. Maintenance of the soft parts deprived of nerve supply and sympathetic infiltrations are auxiliary measures worthy of attention.

Giornale Veneto di Scienze Mediche, Venice

14:129-192 (March) 1940. Partial Index

- *Frequency of Coronary Branch of Right Coronary Artery. G. Tirelli.—p. 149.
 *Cervical Ribs: Clinical and X-Ray Study. M. Belgrano.—p. 155.

Frequency of Accessory Right Coronary Artery.—Tirelli examined in the Civil Hospital of Venice 130 hearts of dead fetuses and of cadavers from birth to the age of 85. He found an accessory right coronary artery in fifty-eight. The right marginal artery was either atrophic or nonexistent in such hearts. The accessory coronary artery had its origin in the intima of the aorta on the left side of the normal right coronary artery, which it paralleled in its course downward along the auriculoventricular sulcus, pursuing the course of the right marginal artery and terminating on the diaphragmatic surface of the right ventricle. The caliber of the accessory artery was like that of the marginal artery. The author believes that the accessory artery is the right marginal artery with an abnormality at its point of origin. It comes off directly from the aorta instead of from the right coronary artery as the right marginal artery does. The existence of the accessory artery is of anatomopathologic importance. It may be obliterated by syphilitic or arteriosclerotic alterations because of its small caliber and cause symptoms similar to those of coronary occlusion.

Cervical Ribs.—Belgrano studied thirty-one cases of cervical rib and six of hypertrophy of the transverse process of the fourth cervical vertebra. There were thirty female and seven male patients. Trauma was the cause in six. Vascular or neurologic manifestations were present in all but six. The most frequent symptoms were unilateral or bilateral pain in the shoulder and arm, frequently associated with muscle atrophy, neck pain, formication, paresthesias, variations in the local temperature and other sensory, motor and vascular disturbances. Acute headache was the predominant symptom in one and cough in five. There was paresis of the dome of the diaphragm in three cases and paralysis of vocal cords in one. The arterial blood pressure was diminished on the involved (or predominantly involved) side as compared with the normal side. The roentgenograms demonstrated the condition to be bilateral in twenty-one cases.

 *Report on Eight Hundred and Eighty-Three Cases of Carcinoma of Stomach Treated During 1921-1932. K. Weese.—p. 202.

Krukenberg Tumors.—In connection with three carefully analyzed cases of ovarian growth diagnosed as Krukenberg tumor, Bittmann discusses their pathogenesis. Solid ovarian tumors were found bilaterally in two of the patients (unmarried,

aged 22 and 25 years). In addition, roentgenoscopy disclosed an intersellar tumor in the patient 25 years old. In the third patient (an octipara aged 60 with an unbroken history of normal deliveries) a neoplastic growth was found only in one ovary; the other ovary showed senile atrophy. However, a solid neoplasm as large as a man's fist was discovered at the pylorus. Microscopic examination of the ovarian tumor demonstrated the presence of "seal ring" cells of a pronounced epithelial character. No tumor cells were found in the lymph nodes. The author regards Krukenberg tumor as predominantly, if not entirely, a malignant primary neoplasm, related to multiple carcinomas. He does not think that they represent metastases either originating in the digestive tract or by way of the lymph nodes. Experiments with single and double tumor cell implantation in a large number of white rats confirmed his hypothesis of a multiple carcinoma. Coexisting tumors wage war on each other which tends to prolong the life of the harboring host, but the removal of one of these at once activates the other into an intensified malignant course at the expense of the host. The long latency of the coexisting solid tumor with no suggestive symptomatology not only argues against the view of carcinomatous metastasis but marks the prognosis of the disease as invariably unfavorable. Radical operations should be followed up with roentgen therapy.

Peritoneal Absorption After Laparotomy.—Rathcke studied in animal experiments and in man the effects of laparotomy on the defense mechanisms of the peritoneum against bacterial infection, especially on the peritoneal absorption. Intraperitoneal injections of trypan blue in guinea pigs showed that laparotomy at first retarded absorption but that, beginning with the second day, absorption was accelerated and continued so for fourteen days. That this increased absorption was due to the enlargement of peritoneal lymph channels was clearly observable in hydrogen peroxide tests. The same enlargement of lymph channels was observed also in the parietal peritoneum of laparotomized animals. Trypan blue was absorbed more readily on the first and second day after laparotomy. Laparotomized animals, on the average, lived three times as long as nonlaparotomized, manifesting increased bactericidal resistance. The stimulation of peritoneal lymph channels and augmented absorptivity could likewise be observed in a number of gastrointestinal ulcer cases selected because no inflammation nor fluid secretions were noted after the first operation. Amniotic and ascitic fluids and physiologic solution of sodium chloride were effective in modifying the lymph channels of the parietal peritoneum and thus increasing immunity. The author concludes that an abdominal operation performed in two stages not only decreases the danger of postoperative peritonitis but increases the patient's resistance for the second and more serious surgical act. This should take place between the fourteenth and twenty-first day after the first laparotomy.

Carcinomas of Stomach.—Weese presents an analysis of 883 carcinomas of the stomach, observed in a university clinic during the course of twelve years. The patients, largely drawn from the rural population, consisted of 586 men (66.36 per cent) and 297 women (33.64 per cent), of whom the youngest was 17 years of age. The predominant disease incidence was in the sixth decade with 221 men (25.08 per cent) and 138 women (15.36 per cent). Only fifty-seven carcinomas (6.45 per cent) occurred below the age of 40. In 530 cases (60 per cent) either no operation (fifty-four) could be performed or palliative measures were adopted, such as jejunostomy (seventy-seven), gastrostomy (forty-two) exploratory laparotomy (124), roentgen therapy alone (thirty-six) and gastro-enterostomy (189). The average span of life, dating from the onset of the symptoms, was 8.73 months for those not operated on, with an average of from four to five months more for those on whom gastrostomy and gastro-enterostomy had been performed. In the remaining 353 cases (40 per cent), consisting of 208 men and 147 women, the second operation of Billroth was performed 339 times and the first operation of Billroth eleven times, chiefly for a pyloric carcinoma (193 cases, equivalent to 54.67 per cent) and for prepyloric carcinoma (seventy-eight cases equivalent to 22.09 per cent). Simple resection requiring the removal of a few adhesions and glandular metastases was done in 225 cases (63.74

per cent), complicated and palliative resection in 128 cases (36.26 per cent). Complicated cases involved chiefly the mesocolon (twenty-four cases) and the pancreas (nineteen); palliative intervention concerned cases in which not all carcinomatous growth and metastases, largely glandular or hepatic, could be removed. Ninety-three postoperative deaths occurred in the resected group, largely from peritonitis (forty, or 45.4 per cent) and pulmonary complications (twenty-eight, or 30.11 per cent). Of the surviving 260 patients, 193 died within five years; sixty-seven lived more than five years (in fifty-six of these cases simple resection had been performed). Jejunostomy showed the highest postoperative mortality. Roentgen treatments with massive single or fractionated doses employed in cases in which operation could not be performed did not prolong life; however, roentgen therapy in postoperative cases seemed to contribute to prolongation. Palliative measures had only an insignificant effect on the duration of life. Prognosis was more favorable in women than in men and in carcinomas of the cylindric cell type.

*Five Hundred and Eighty-Seven Thoracoplasties Observed for Seventeen Years or Less. Steglich.—p. 351.

Five Hundred and Eighty-Seven Thoracoplasties.—Steglich's report is a comparative evaluation of data furnished by a number of hospitals and sanatoriums in response to a questionnaire regarding thoracoplasties performed on tuberculous patients. The observations cover a period of seventeen years, varying with the individual case, and affect the age level between 8 and 56 years. The dominant points of view controlling the analysis are the extent to which life was preserved by total and partial thoracoplasty, the number of healed lesions and the extent of restoration to occupational usefulness. Total thoracoplasty with resection of eleven ribs was performed in 230 cases and constituted the leading surgical method until it was surpassed in 1933 by the eight rib surgery of the upper thorax, performed in sixty-five cases. A remarkably high mortality was noted for total (eleven rib) thoracoplasty, 115 (50 per cent) of the 230 patients dying as compared with sixteen deaths (27.1 per cent) out of sixty-five for the eight rib resection and thirteen deaths (21.3 per cent) out of sixty-one cases for subtotal (ten rib) operation. The mortality rate was highest in the first two years, especially the first, 97 per cent of the men and 94 per cent of the women dying from tuberculosis or postoperative complications. After these two critical years the death rate for men is highest in the seventh year and for women in the ninth. Of 342 persons operated on and alive in 1936 (165 men, 177 women) 210 showed healed lesions (men 59.1 per cent, women 65.5 per cent), respectively 61.4 per cent of the living and 36.4 per cent of all patients operated on. Small cavitations and unilateral infections showed greater susceptibility to improvement. Of those living, 54.2 per cent, equivalent to 31 per cent of those operated on, were occupationally restored or rehabilitated, with unskilled labor and farm workers at a disadvantage. Figures for the economic rehabilitation of the women impair statistical calculations because a large percentage did domestic work at home. Four of the five women who later gave birth to children were reported in good health. According to the author the proper appraisal of the success of thoracoplasties should, on the average, allow five years for vitality rate evaluation and from six to seven years for the healing of lesions. Operations offer best prognosis if performed within the 20 to 40 year age level; open lesions, however, existing for more than twelve years present a predominantly unfavorable outlook. The therapeutic value of thoracoplasties must be judged not only by the number of lives saved but by the number of open lesions that become bacillus negative and furthermore by the fact that the mortality rate is only from 40 to 50 per cent instead of from 80 to 90 in cases of open infection.

*Clinical Course of Diphtheria in Actively Immunized Children. L. Herding.—p. 86.

Active Antidiphtheria Immunization in Children.—Herding reports the successful use of antidiphtheria vaccination in 700 children between the ages of 2 and 14 years, in whom only twenty (3 per cent) developed the infection but recovered. The children were inmates of a children's home and had been under observation for two years at a time when no epidemic occurred either in the home or in the vicinity. Eighteen cases presented diphtheria positive smears at the outset. Inoculation took place, on the average, from four to five weeks before infection set in; dosage consisted of from 4,000 to 8,000 antitoxin units with the exception of one case, in which 16,000 units was administered. The children exhibited little or no local reaction to the first treatment or in most cases to the second. Seventeen of the twenty cases were light attacks and progressed favorably, although four of them were complicated by scarlatina, bilateral otitis, diphtheric otitis media or scrofulosis. No cardiac or circulatory disturbances of consequence were noted. In three cases recovery was delayed. The single serious case was one of myocardial involvement and paresis of one leg. The author calls particular attention to the fact that in sixteen of the twenty cases tonsillar pathologic change was not typical of diphtheria. Only three patients exhibited typical foci; the fourth, an atypical coating that developed into a diphtheric membrane. The appearance of the tonsils was likewise not typical for diphtheria but was of a dirty grayish yellow. He regards the low incidence rate as a positive result of an active immunization.

Antirabies Inoculation: Report of State Institution in Vienna for 1927-1938. W. Piringer.—p. 150.

Thyroidectomy and "Oxygen Debt" in Heart Disease.—According to Siedek, total ablation of the thyroid in eight selected cases of cardiac insufficiency was found to reduce the relative "oxygen debt." By relative oxygen debt is meant the quantity of oxygen used during the second to the seventh minute after cessation of effort in exercise tests. Oxygen consumption was measured both before and after total thyroidectomy. The procedure was carried out in the morning after bed rest and before food ingestion. The patients ascended a certain number of steps within a specified time. The Douglas sac method and Haldane's apparatus for determining oxygen values were employed. A significant oxygen reduction from 210 to 90 per cent was noted in one case. The diminution of oxygen consumption was accompanied in all cases by an improvement in subjective symptoms. The author believes that cardiac sufficiency is more adequately determined by measurements made after cessation of effort during the ensuing rest period than by measuring the increased consumption of oxygen during effort.

Experimental Contributions to Pathogenesis of Septic Thrombosis. I. Györfy.—p. 237.

Curettage in Extra-Uterine Pregnancy.—Willer cites two cases which illustrate the diagnostic value of the microscopic examination of the curettage material. Changes observed in 161 curettage specimens are presented. Curettage had been

performed in some of the cases because extra-uterine pregnancy was suspected and in others for different reasons. Study of the curettage material either confirmed or ruled out extra-uterine pregnancy in all but twenty-two cases. In the latter, erroneous results were obtained. Ten of these cases were "no failures" in the sense that the microscopic appearances contradicted an extra-uterine pregnancy when one did exist. In the other twelve, the "yes failures," the curettage material erroneously indicated the presence of an extra-uterine pregnancy. The author concludes that the microscopic examination of the curettage material does not furnish definite proof of an extra-uterine pregnancy; conversely, there is no microscopic appearance which permits the exclusion of an extra-uterine pregnancy. The author enumerates tissue changes in curettage material found in normal pregnancy, in abortion after intra-uterine pregnancy, and in extra-uterine pregnancy. A comparison of the state of the decidua, of the presence or absence of inflammation, of fibrinoid necrosis and of changes in the vascular walls, in the epithelium and in the pregnancy glands reveals that there are no definite signs to permit a differentiation. Doubtful cases are sufficiently numerous to justify a microscopic examination.

*Results of Administration of New Anticonvulsive Preparation Epanutin (Dilantin Sodium). A. K. A. Gijssberti Hodenpijl.—p. 252.

Therapeutic Results of Dilantin Sodium.—Gijssberti Hodenpijl describes the results obtained with dilantin sodium in ten children with epileptiform attacks resulting from trauma at birth, encephalitis and meningitis, or with pyknolepsy or salaam convulsions. The children varied in age between 5 months and 9 years. The smallest daily dose was 50 mg. and the largest 400 mg. Convulsions disappeared in six children; in one the treatment failed, presumably because the doses were too small; in the other three the frequency of the attacks decreased at first but later the medication was no longer effective. Signs of intoxication in the form of somnolence, vomiting and diarrhea appeared in five, and an urticaria-like exanthem developed in one. These symptoms were temporary. Results did not come up to the author's expectations. The secondary effects were not as negligible as earlier reports had indicated. He suggests that with continuous use they might become less noticeable, as indicated by several of his cases.

Serum Therapy in Diphtheria.—Bie analyzes observations on 15,448 patients with pseudomembranous pharyngeal diphtheria treated at the Blegdam hospital, Copenhagen, during the period 1920-1934. In 72 per cent the disease was mild, in 22 per cent of moderate severity and in 6 per cent severe. Toxic symptoms were frequent in the severe form of diphtheria. Ninety-five per cent of this group had fetor, 84 per cent periglandular edema, 29 per cent hemorrhagic diathesis and 53 per cent albuminuria. The following principles were adhered to in the treatment: 1. Serum was injected as soon as possible after the diagnosis

had been made. 2. The entire quantity of serum was given in one or, at the most, in two doses. 3. A large portion was injected intravenously, the remainder intramuscularly. 4. The severe cases were treated with a large dose, approximately 200,000 units of antitoxin. The author gained the impression that nothing is to be gained by administering more than from 200,000 to 300,000 units. The average mortality rate for the entire material was 2.6 per cent, but, disregarding the patients who died within the first twenty-four hours after hospitalization, it was 1.9 per cent and for the three groups of cases (mild, moderate and severe) it was 0.05, 2.9 and 21.4 per cent, respectively. It was found that 20 per cent of the severe cases occurred in children of 4 years or less, 48 per cent in children of the age group from 5 to 9, 20 per cent in those of the age group 10 to 14 and 12 per cent in persons over 15 years of age. The mortality was greatest among children of the first five years of life.

Functions of Fetal Thyroid.—Zondek reports a case of myxedema in which a woman after two years of treatment with thyroïdin became pregnant and gave birth to a normal child. Thyroïdin controlled her symptoms during the three first months of gestation. The heart, however, showed slight dilatation of the left ventricle, flattening of the PT deflection and lowering of the RS complex as the first indication of a beginning relapse. Since these changes became apparent during thyroïdin treatment, it was believed that the pregnancy had an injurious effect on the maternal thyroid. Thyroïdin treatment was now discontinued but, contrary to expectation, no further symptoms appeared up to the period after delivery. In the ninth month of gestation the basal metabolic rate was minus 1 per cent. The heart showed the same aspects as ascertained in the third month. Shortly after delivery, however, typical symptoms of myxedema reappeared (marked puffiness of the face, swelling of the eyelids, hands and feet, low and rough voice). Six weeks after delivery the basal metabolic rate was minus 29 per cent and the typical myxedema heart was now present. Thyroïdin treatment was again administered and improvement of all these symptoms took place once more. Zondek believes that the relapse after termination of pregnancy must be associated with the fact that substitutive activity of the fetal thyroid gland which existed during the last months of pregnancy was no longer present.

Tubercle Bacilli in Nodules of Erythema Nodosum.—Erythema nodosum has been in the past regarded as a non-specific allergic phenomenon and this opinion is accepted by the majority of pediatricians and dermatologists. Wallgren and Gnosspelius made bacteriologic studies of the nodules of erythema nodosum of twenty-eight children giving a positive tuberculin reaction. In the majority of cases the efflorescences were excised from twenty-four to forty-eight hours after their appearance. The tissue was ground under aseptic conditions, treated for twenty minutes at a temperature of 37 C. with a 4 per cent solution of sodium hydroxide, centrifuged, and neutralized with hydrochloric acid. Cultures and inoculations into guinea pigs were made. The majority of the animals were tuberculin tested before and about two months after the inoculation. The animal test was positive in only one of the twenty-eight cases. The authors cite similar experiments of other investigators in which out of 113 cases positive results were obtained in four. The authors feel that the question whether the presence of tubercle bacilli proves that the erythema nodosum nodule is a specific tuberculous and local process must be answered in the negative. They cite cases giving a negative as well as cases giving a positive tuberculin reaction. They stress that the eruption of erythema nodosum is clinically and anatomically identical in the two cases although the allergy provoking agent is perhaps different. The evolution of an erythematous eruption and the histologic structure of the nodule are not identical with the specific tissue changes produced by the tubercle bacillus. Even if the tubercle bacilli were constantly demonstrable in the nodules, the structure of the erythematous exanthem would indicate that the mode of reaction to the tuberculous virus is entirely different than under ordinary conditions. This different mode of reaction is determined by allergy. Because the bacilli are encountered exceptionally, it must be doubted that they usually are concerned in the development of the nodule. Their presence must be regarded as an accidental manifestation.

REGURGITATION JAUNDICE

CLINICAL DIFFERENTIATION OF THE COMMON
FORMS, WITH PARTICULAR REFERENCE TO
THE DEGREE OF BILIARY OBSTRUCTION

C. J. WATSON, M.D.
MINNEAPOLIS

The recognition of two main varieties of jaundice, namely retention and regurgitation jaundice according to Rich's classification,¹ is of fundamental value. The presence of bilirubin in the urine, likewise the finding of a prompt van den Bergh reaction, at once identifies regurgitation jaundice and separates it from retention jaundice, in which there is simply a hepatocellular inability to dispose of bilirubin provided from the circulating blood. In retention jaundice hepatocellular function may be regarded as sluggish as far as bilirubin excretion is concerned.² This sluggishness is more or less relative in hemolytic icterus (one of the principal representatives of the retention type) but must be considered absolute in the rare condition best known as constitutional hepatic dysfunction.³ In retention jaundice bilirubin alone is held back and accumulated, while in regurgitation jaundice there is the fundamental difference that whole bile returns to the blood. There is much reason to believe that this regurgitation of bile occurs in one of two ways:⁴

1. There is increased intrabiliary pressure due to obstruction of the bile ducts from one cause or another. Rhexis of the small biliary radicles, particularly of the weaker, ampullary portions of the bile capillaries results, and the bile thus gains access to the adjacent lymph spaces.⁵

2. There is increased permeability of the bile capillaries with leakage or diapedesis of bile into the lymph spaces. Again it appears that the ampullary portions

of the bile capillaries are the areas most susceptible of injury and hence the chief sites of increased permeability and regurgitation. Injury of this type is undoubtedly caused by a great variety of poisons and toxins. Among others, toluylenediamine, neoarsphenamine, cinchophen and sulfanilamide may be mentioned.

The separation of jaundice into retention and regurgitation types, while thus of fundamental importance, is not adequate for purposes of clinical diagnosis and management of patients. Regurgitation jaundice is characteristic of any severe diffuse liver damage. It is equally characteristic, however, of biliary obstruction due to common duct stone or to cancer. The diverse management of these conditions requires that regurgitation jaundice be subdivided into three main groups: (1) cancerous, (2) calculous and (3) parenchymal types. In my experience, based on the material to be discussed, this subdivision of regurgitation jaundice has been of much value especially from a practical standpoint. It is true that there are certain causes of regurgitation jaundice, such as benign stricture of the common duct, chronic pancreatitis and benign tumor and cysts, which are not readily included in these subdivisions and require individual consideration. The vast majority of cases encountered, however, can be so classified without difficulty. My purpose in this report is to summarize experience with various means of differentiating the three main groups of regurgitation jaundice, with particular reference to urobilinogen excretion. This experience has been gained during the past seven years, in which somewhat more than 300 cases of jaundice of all types have been observed.

MATERIAL AND METHODS

The cases composing the material for the present study were divided as follows:

1. Cancerous jaundice, sixty-seven cases.
 - (a) Primary or metastatic cancer in the biliary tract causing obstruction of the common bile duct, the common hepatic duct, or of both right and left hepatic ducts, fifty-eight cases, as follows:
 - Carcinoma of head of pancreas, twenty-three.
 - Carcinoma of common bile duct, eleven.
 - Carcinoma of cystic duct involving common duct, one.
 - Carcinoma of gallbladder extending into common duct, three.
 - Carcinoma metastases in common duct or liver involving main hepatic ducts, nine.
 - Carcinoma having origin in biliary tract, exact primary site not determined, nine.
 - Malignant melanoma metastases to common bile duct (polypoid type), one.
 - Retroperitoneal sarcoma involving common bile duct, one.
 - (b) Diffuse or very widespread nodular metastatic carcinoma of the liver, nine cases. (As will be noted, the jaundice in these instances was moderate or slight, and in general the clinical features were often more like those of parenchymal jaundice.)

3. Rozendaal, H. M.; Comfort, M. W., and Snell, A. M.: Slight and Latent Jaundice: The Significance of Elevated Concentrations of Bilirubin Giving an Indirect van den Bergh Reaction, *J. A. M. A.* 104: 374 (Feb. 2) 1935. Watson.²

4. Itoh, Tadasi: Experimentelle Studien über die Pathogenese des Toluylenediaminikterus, *Beitr. z. path. Anat. u. z. allg. Path.* 86: 498 (May 29) 1931; Experimentelle Beiträge zur Pathogenese des Phenylhydrazinikterus, *ibid.* 89: 513 (July 5) 1932. Hiyeda, K.: Experimentelle Studien über den Ikterus: Ein Beitrag zur Pathogenese des Stauungsikterus, *Beitr. z. path. Anat. u. z. allg. Path.* 73: 541, 1925; Experimentelle Studien über die Pathogenese des Ikterus: Ueber die Entstehung des Toluylenediaminikterus, *ibid.* 78: 389 (Sept. 5) 1927.

5. The existing evidence favors the view that the regurgitated bile in both process 1 and process 2 passes chiefly by way of the lymphatics and thoracic duct into the blood stream (Bloom, William: The Role of the Lymphatics in the Absorption of Bile Pigment from the Liver in Early Obstructive Jaundice, *Bull. Johns Hopkins Hosp.* 34: 316 [Sept.] 1923. Hiyeda⁴).

- 2. Calculous jaundice, sixty-one cases.
- 3. Parenchymal jaundice, fifty-seven cases.⁶
 - (a) Cirrhosis hepatis, twenty-eight cases.
 - (b) "Catarrhal" jaundice, twenty-three cases.
 - (c) Acute or subacute atrophy, five cases.

In addition to the cases just classified, there were five instances of benign (postoperative) common duct stricture and two of chronic pancreatitis with jaundice.

Chart 1.—Icteric index and urobilinogen excretion in feces and urine in the common forms of jaundice, expressed in units (icteric index) or milligrams (urobilinogen). The shading indicates the normal range. Group I: cancerous jaundice, fifty-three cases, operation or autopsy in 60 per cent. Group II: calculous jaundice, sixty-one cases, operation or autopsy in 56 per cent. Group III: parenchymal jaundice, fifty-seven cases, autopsy in 19 per cent.

The diagnoses in these cases were based in part on postmortem or operative evidence and in part on clinical study only. The percentage of cases in which the diagnosis was verified at operation or autopsy is given in the legend for chart 1. The relatively low percentage in group 3 (the parenchymal group) is accounted for by the considerable number of cases of catarrhal jaundice which were included and in which recovery took place. Cases are not included in the present analysis if the diagnosis was made on clinical grounds alone unless the various data and the outcome clearly indicated the nature of the disease.

Particular attention was given throughout this study to the degree of jaundice and to the per diem excretion of urobilinogen in feces and urine. The data for some of the cases in the list were reported in an earlier communication dealing with urobilinogen excretion.⁷ For statistical analysis, however, these cases are included in the present report.

The icterus index was determined by colorimetric comparison of the suitably diluted blood serum with a 1:10,000 potassium bichromate solution. The normal range is believed to be from 5 to 10. The per diem excretion of urobilinogen in feces and urine was determined by my modification⁸ of Terwen's procedure.⁹

6. Cases of jaundice due to parenchymal liver damage on the basis of severe infection and those due to sulfanilamide come under this heading but are not included in the present study. (Watson, C. J., and Spink, W. W.: The Effect of Sulfanilamide and Sulfapyridine on Hemoglobin Metabolism and Liver Function, Arch. Int. Med. 65:825 [April] 1940).

7. Watson, C. J.: Studies of Urobilinogen: III. The Per Diem Excretion of Urobilinogen in the Common Forms of Jaundice and Disease of Liver, Arch. Int. Med. 59:206 (Feb.) 1937.

8. Watson, C. J.: Studies of Urobilinogen: I. An Improved Method for the Quantitative Estimation of Urobilinogen in Feces and Urine, Am. J. Clin. Path. 6:458 (Sept.) 1936.

9. Terwen, A. J. L.: Ueber ein neues Verfahren zur quantitative Urobilin Bestimmung im Harn und Stuhl, Deutsches Arch. f. klin. Med. 149:72 (Nov.) 1925.

The method was applied to one or more twenty-four hour urine specimens and to one or more four day collections of feces. It is essential that the four day collection include at least 250 Gm. of relatively solid feces. If enemas have been used, the liquid and solid portions are separated and a determination is carried out on each, provided the solid portion weighs at least 250 Gm. If less than this is present in the collection, it is believed either that some has been lost or that constipation has been so marked as to prevent any accurate conclusions. In the presence of diarrhea, determinations are of value with respect only to biliary obstruction, not to the rate of blood destruction. I am aware of the recent paper of Sparkman¹⁰ advocating that the determination be carried out on individual samples of feces or urine and that the values be expressed in terms of milligrams per hundred grams or hundred cubic centimeters. Although this appears to make for simplicity, there are a number of objections to Sparkman's procedure, which will be considered in a separate communication.

RESULTS

It is believed unnecessary to give in detail the exact data for the icterus index and urobilinogen excretion in the various cases of regurgitation jaundice. Sufficient representative data of this type have been provided in a previous communication.⁷ For purposes of comparison, all the data thus far obtained have been divided into a number of different groups, each representing a certain range of values. In chart 1 may be seen the range of values for the icterus index and the amount of urobilinogen in the feces and urine in the cases of all three groups of regurgitation jaundice. Data relating to jaundice and urobilinogen excretion were obtained from thirty-three cases of carcinomatous metastases to the liver. These cases have been divided into three groups as shown in chart 2.

Chart 2.—Icteric index and urobilinogen excretion in feces and urine in thirty-three cases of carcinomatosis of the liver, expressed in units (icteric index) or milligrams (urobilinogen). The shading indicates the normal range. Group I: little or no jaundice, discrete metastases. Group II: mild or moderate jaundice, confluent nodular or diffuse metastases. Group III: marked jaundice, involvement of main hepatic ducts or common bile duct by metastases.

In table 1 are shown the results of the study of five cases of postoperative common duct stricture. The pertinent data in the two cases of chronic pancreatitis are

10. Sparkman, Robert: Stur... A Simple and Rapid Method for Quantitative Determinations of Urobilinogen Content of Single Specimens of Urine and Stool, ibid. 63:872 (May) 1939.

given in table 2. These patients were observed with particular reference to urobilinogen excretion in the feces—in other words, with respect to the degree of biliary obstruction—in order to permit comparison with the results obtained in the cancer group.

COMMENT

1. *The Degree of Biliary Obstruction.*—It has often been assumed that the intensity of jaundice is dependent chiefly or solely on the degree of biliary obstruction. (The term biliary obstruction will be used in the broad

sense to denote any intrahepatic or extrahepatic interference with bile flow.) As a matter of fact this is only one of several important factors, and it is therefore desirable that the intensity of icterus and the degree of biliary obstruction be considered separately.

In group I (chart 1) it will be noted that in forty-nine of fifty-three cases of cancer involving the biliary tract there was complete biliary obstruction. This is arbitrarily defined as less than 5 mg. of urobilinogen daily in the feces.¹¹ According to this definition, 92 per cent of the cases in group I showed complete biliary obstruction, and in 55 per cent there was less than 1 mg. of urobilinogen a day in the feces. This is particularly significant when contrasted with the number of such cases in the noncancerous groups II and III (chart 1). In but two instances in these groups, in other words in 1.7 per cent of 118 cases, was there less than 1 mg. of feces urobilinogen a day. Both of the patients had common duct stones. In five additional instances in group II the per diem amount of the feces urobilinogen was less than 5 mg. This constitutes a total of seven, or 11.5 per cent, of the group of sixty-one cases. The exact incidence of cases of complete obstruction is undoubtedly lower than this, however, since many cases of common duct stone with but slight jaundice observed during the same period of time were not investigated as regards per diem urobilinogen excretion. On the other hand, relatively very few cases of biliary tract cancer were omitted from the study. In group III, consisting of fifty-seven cases of parenchymal jaundice, there were but two, or 3.5 per cent, exhibiting less than 5 mg. of feces urobilinogen per day. There were but four cases in the biliary tract cancer group (I) in which more than 5 mg. a day was found. In one of these,

in which cancer of the gallbladder extending into the common duct was proved at operation, the average amounts in two successive four day periods were 7.2 and 7.5 mg. This is regarded as too much to represent pigment derived from bile stained mucosa and probably indicates that the biliary obstruction was almost, but not quite, complete. In two of the four cases there were polypoid tumors of the common duct which because of their soft, sessile structure permitted egress of a certain amount of bile. In one of these cases, studied over a considerable period of time, complete obstruction was intermittent and it appeared that the polypoid tumor had behaved as a ball valve. In the fourth case there was much reason to believe that the patient had a very small internal biliary fistula. On x-ray study gas was observed in the biliary tract; it was not possible, however, to demonstrate a fistula by means of a barium sulfate meal or enema. This patient had relatively little icterus, the icterus index being 26. At operation it was determined that there was a large hard carcinoma in the head of the pancreas extending up into the common bile duct. The surgeon did not observe any internal biliary fistula but stated that it might well have been present but unrecognizable. Later biopsy of a cervical lymph node revealed adenocarcinoma.

In chart 1 it will be noted that the twenty-four hour urine urobilinogen was less than 1 mg. in fifty-one of the fifty-three cases. As a matter of fact the amount was less than 0.3 mg. in forty-eight cases, or 90 per cent of the entire group. This is in particular contrast with the results in group II (parenchymal jaundice), in which there were but six cases showing less than 1 mg. a day, of which four, or 7 per cent of the entire group, exhibited less than 0.3 mg. a day. Absence of urobilinogen from the urine in patients with jaundice is not safe evidence that there is complete interference with bile flow. In many cases of calculous jaundice with incomplete biliary obstruction, urobilinogen is either

TABLE 2.—Chronic Pancreatitis with Jaundice

Patient	Course of Illness	Necropsy
Case 1 ♂ aged 62	Painless jaundice 6 mo.; icteric index 51; fecal urobilinogen 76.6 mg. per day; urinary urobilinogen 5.7-21.4 mg. per day; severe diabetes. Cholecystectomy; cholecystitis, cholelithiasis, cholechochitis, chronic pancreatitis; died 1½ yrs. after operation	Severe diffuse chronic suppurative pancreatitis; hypoglycemic cerebral damage
Case 2 ♀ aged 71	Painless jaundice and pruritus 1 mo.; clay colored stools, dark urine; easily palpable nontender distended gallbladder; icteric index 116-162; fecal urobilinogen 9.4-22 mg. a day; no urinary urobilinogen. Cholecystogastrostomy because of hard nodular head of pancreas, believed carcinomatous; death from hemorrhage 1 week after operation	Chronic pancreatitis

absent from the urine or not appreciably increased. A few cases of parenchymal jaundice have been observed in which the feces urobilinogen ranged from 10 to 20 mg. a day, rarely even higher than this, but with complete absence of urobilinogen from the urine. It could only be assumed in these cases that reabsorption of urobilinogen from the bowel was faulty, or that the liver, even though damaged, was yet capable of disposing of small amounts of urobilinogen which were reabsorbed.

Reference has been made in a previous communication⁷ to the probable basis for the striking difference in the degree of biliary obstruction usually noted in cancerous as contrasted with calculous or with parenchymal

11. Very small amounts of urobilinogen are undoubtedly derived at times from the bilirubin of bile stained epithelial cells of the colon (Gerhardt, Dietrich: Ueber Urobilin, Ztschr. f. klin. Med. 32: 303, 1897; Wallace, G. B., and Diamond, J. S.: The Significance of Urobilinogen in the Urine as a Test for Liver Function, Arch. Int. Med. 35: 698 [June] 1925; McMaster, P. D., and Elman, Robert: Studies on Urobilin Physiology and Pathology, J. Exper. Med. 41: 513 [April] 1925). The amount which might be derived in this way has never been ascertained with certainty, but it is probably never greater than 5 mg. a day and rarely as much as that.

jaundice. Briefly stated, this is the progressively stenosing or compressing effect of neoplastic disease, differing markedly from the constantly dilating effect of a common duct stone. One might expect certain exceptions in cases of impacted calculi, but so far at least this has not been true in my experience. Cases of gallstones tightly impacted in the ampulla of Vater, without complete biliary obstruction, were described in an earlier report.⁷ The two most notable exceptions in the entire series to date were cases in which common duct stones were loose in the duct but were nevertheless associated with complete exclusion of bile from the intestine. The data from one of these cases are shown in table 3.

It will be noted that there was considerable evidence of hepatocellular dysfunction in this case. The galactose test was positive and the stercobilin tolerance¹² was markedly reduced. It seems likely that there was an associated disturbance in the secretion of bile, which together with the calculous obstruction would then readily explain the persistent absence of urobilinogen from the feces during the first four periods. Evidence

of liver dysfunction was also observed in the other of the two exceptions mentioned.

In parenchymal jaundice, urobilinogen seldom disappears from the feces for any consecutive four day period, presumably because a complete suppression of bile flow of this duration is relatively rare. There can be no doubt, however, that this does occur now and then in acute catarrhal jaundice at the height of the disease; furthermore, it is seen in some instances of acute or subacute atrophy of the liver. In one of the five cases of atrophy in the present series, there was complete cessation of bile flow (1.9 mg. of feces urobilinogen a day).

The results in table 1 indicate that traumatic stricture of the common bile duct may or may not be associated with complete biliary obstruction. In one of the cases it is seen that the icterus was of relatively low intensity and the urobilinogen of the feces was actually increased on repeated examinations. The significance of this increase is not clear, but it was probably not due to temporary release of obstruction such as is often observed with common duct stone (as exemplified by the cases in chart 1, in which the feces urobilinogen was above 200 mg. a day). It was considered likely

that the increase in this case was due to increased blood destruction related to severe infection and fever (cholelitis).

In the two cases of chronic pancreatitis with jaundice included in this series the biliary obstruction was not complete (table 2). In the second of these cases the diagnosis was rendered particularly difficult because of an easily palpable, distended and nontender gallbladder. A palpable gallbladder of this smooth and nontender variety has been encountered in only one other case in which there was incomplete biliary obstruction. This was the case already referred to, of a carcinoma of the head of the pancreas, in which there was x-ray evidence of an internal biliary fistula. These two instances make it clear that complete biliary obstruction is not essential to the presence of a palpable, distended gallbladder. The possibility of chronic pancreatitis as the cause of jaundice should be considered in the presence of incomplete biliary obstruction and a palpable gallbladder of the type just mentioned. In my experience this type is usually distinguished with a considerable degree of certainty from the palpable gallbladders due to empyema, hydrops, large calculi or primary carcinoma. The first two of the latter varieties are much more vague and are tender as a general rule; muscle spasm is noted in the cases with more active inflammation. The palpable gallbladder due to a large stone in the fundus is very hard and often irregular; the same may be said for primary carcinoma of the gallbladder. It may be emphasized that a nontender, smooth distention of the gallbladder is a sign (Courvoisier's) of cancerous biliary obstruction that is too frequently overlooked; when it exists in association with complete biliary obstruction (less than 5 mg. a day of feces urobilinogen) there can be little doubt that the jaundice is due to cancer. I have encountered no exception to this.

2. *The Intensity of Jaundice.*—In chart 1 it is seen that the jaundice was more often intense in cases of biliary obstruction due to cancer (group I) than in the calculous or parenchymal groups. This is, of course, an observation that has often been made in the past. While in the majority of cases in group I the icterus index was above 100, in a considerable proportion it is seen to be between 50 and 100 and in a few between 20 and 50. It is undoubtedly true that jaundice due to cancer in the biliary tract is likely to be of sufficient degree so that the icterus index is above rather than below 100 and that calculous jaundice, on the contrary, rarely has an icterus index above 100; nevertheless there is enough overlapping so that a sharp separation cannot be made on this basis. The icterus index in the series of cases of parenchymal jaundice (group III in chart 1) exhibits an even wider range, and the intensity of jaundice is of little or no value in distinguishing this group.

In the presence of complete biliary obstruction there are two factors which determine the intensity of jaundice. The first and perhaps the most important of these is the rate and manner of hemoglobin wastage. It has been established definitely by Rous and Drury¹³ that loss of blood in dogs having complete biliary obstruction is followed by a decrease in the intensity of icterus, probably resulting from a compensatory throttling of the rate of blood destruction. Conversely, an increase in the rate of blood destruction, such as may be induced by hemolytic agents, is followed by an increase in the

12. Watson, C. J.: Fate of Parenterally Administered Crystalline Urobilin; Urobilin Tolerance Test of Liver Function, *Proc. Soc. Exper. Biol. & Med.* 34: 377 (April) 1936.

13. Rous, Peyton, and Drury, D. R.: Jaundice as an Expression of the Physiological Wastage of Corpuscles, *J. Exper. Med.* 41: 601 (May) 1925.

intensity of icterus. Reference has been made in an earlier report⁷ to human examples of this effect of blood loss in reducing the degree of jaundice, also to the importance of increased hemolysis in some cases of parenchymal jaundice in which the icterus index is very high in spite of the fact that considerable bile is obviously entering the intestine. (The feces urobilinogen may be markedly increased in spite of a high icterus index. This was true in a number of the cases of group III in chart 1, in which the value for the feces urobilinogen was in excess of 200 mg. a day.)

The second of the two factors mentioned is the excretion of bilirubin in the urine. Loss of bilirubin in the urine constantly tends to decrease the intensity of jaundice. If the production of bilirubin diminishes, it is clear that the degree of jaundice will rapidly lessen because of bilirubinuria. So far as can be determined this important factor has never been investigated quantitatively with adequate methods in a series of cases of proved complete biliary obstruction.

Jaundice is absent or slight in the majority of cases of metastatic carcinomatosis of the liver. The data presented in chart 2 cannot be regarded as adequate indication of the true proportion with little or no jaundice, since many cases of carcinomatosis of the liver without jaundice were not included in the present study. On the other hand, an attempt had been made to include all cases¹⁴ with definite jaundice, and relatively very few have been omitted. From the present study it is evident that cases of hepatic carcinomatosis may be divided into three groups (chart 2). This division, of course, is not absolute, and it is obvious that any one case might be classified with any one of the three groups at various periods of the disease. In most of the present cases, however, the classification remained the same throughout the period of observation. The type of case in group II is that which is most easily confused with parenchymal jaundice, particularly with cirrhosis of the liver, principally because of mild jaundice, urobilinogenuria and frequently ascites. The very diffuse type of carcinomatosis sometimes encountered in the livers in these cases may even be mistaken at necropsy for cirrhosis of the liver (until the correct diagnosis is established microscopically). Biliary obstruction was but partial in the cases of group II. The feces urobilinogen was not determined except in cases with considerable icterus. In the cases of group III in chart 2, however, complete biliary obstruction occurred because of metastatic lesions involving the main hepatic ducts. These five cases are also included with the fifty-three cases of biliary tract cancer in chart 1.

3. *Urobilinogenuria and Associated Evidence of Diffuse Parenchymal Liver Damage.*—As already noted, complete biliary obstruction (group I, chart 1) is characterized by an absence of urobilinogen in the urine, although this feature alone is not sufficient evidence that the obstruction is complete.

The present data indicate that urobilinogenuria present after the first few days of jaundice is strong evidence against the presence of cancer in the extra-hepatic biliary tract. No case has been encountered in which it appeared that urobilinogen was being formed and absorbed from the biliary tract itself, as noted in dogs by McMaster and Elman.¹⁵ (Clinical proof of this requires urobilinogenuria in the presence of complete biliary obstruction.)

In the calculous and parenchymal groups of jaundice (chart 1) marked urobilinogenuria was often observed. In general, the amounts were not large in cases of common duct stone unless there was associated acute biliary tract infection such as cholecystitis, empyema of the gallbladder or cholangitis, or unless the biliary obstruction was of more than several weeks' duration, resulting in marked enlargement of the liver (biliary or obstructive cirrhosis in many instances). It must be emphasized, however, that while urobilinogenuria was much more often observed in marked degree in the parenchymal group, too much overlapping is noted to permit differentiation on this basis alone. In the distinction of cases belonging in the parenchymal group, several additional clinical features which are often associated with urobilinogenuria may be emphasized.

1. The amine odor, or foetor hepaticus.¹⁶ This has been noted in marked degree only in acute or subacute atrophy of the liver. It has been noted in much fainter concentration in several cases of protracted severe jaundice of catarrhal type in which the jaundice eventually disappeared, also in cases of chronic hepatic cirrhosis with jaundice. Recently the foetor hepaticus has been observed for one or two days in very ill patients with transient jaundice appearing after administration of sulfanilamide. These individuals recovered. The amine odor in mild degree is therefore not always a fatal prognostic sign.

2. Spider nevi.¹⁶ These are regarded as very suggestive of hepatic cirrhosis. They are readily distinguished from ordinary telangiectases, dilated venules or varices. They may be small and easily overlooked, but even the small ones exhibit the characteristic central angioma, with a varying number of very fine vessels radiating outward. Pulsation of larger angiomas of this type has been observed.¹⁷ In accordance with Eppinger's extensive experience,¹⁶ I have not observed spider nevi except in the regions drained by the superior vena cava. The reason for this is as yet unknown. It should be emphasized that these angiomas often appear within the course of a few days, at times even in small groups. They may be noted on the back of the neck or shoulders, and even on the arms and hands. In my experience, typical multiple spider nevi have not been observed except when there was distinct evidence of liver disease.

3. Physical signs of a small liver. Failure to palpate the liver together with very distinct reduction in liver dulness in the midclavicular line is important evidence that the jaundice is of parenchymal type, either cirrhosis or atrophy.

4. Palpable spleen. While this occurs much more frequently in cases of the parenchymal group, it has been noted in several patients with long standing calculous jaundice (with obstructive cirrhosis) and in occasional cases of carcinomatosis. Hodgkin's disease with jaundice is another possibility to be considered. I have studied two cases, not included among the foregoing, in which there were enlarged spleen and liver, deep jaundice and complete biliary obstruction, explained at necropsy by a tight collar of lymph nodes about the common duct; microscopic examination in both instances showed Hodgkin's disease.

17. Williams, D. H., and Snell, A. M.: Pulsating Angioma (Generalized Telangiectasia) of the Skin Associated with Hepatic Disease, *Arch. Int. Med.* 62: 872 (Nov.) 1938.

5. Ascites. This occurs commonly in both parenchymal and cancerous jaundice. In the latter the fluid usually has a specific gravity above 1.014 and is often found to contain mucin, the presence of which is of considerable diagnostic aid. Ascites has been encountered in three cases of long-standing calculous jaundice with secondary obstructive cirrhosis. This is mentioned simply because it indicates that the presence of ascites does not wholly exclude a common duct stone as the underlying, primary cause of jaundice.

SUMMARY AND CONCLUSIONS

1. Regurgitation jaundice may be divided from a clinical standpoint into three main groups: (a) cancerous, (b) calculous and (c) parenchymal.

2. The common variety of jaundice due to cancer is that in which the extrahepatic biliary tract is involved either primarily or by metastatic tumor. In 92 per cent of the cases in this group there was complete biliary obstruction (less than 5 mg. of feces urobilinogen daily). Of the combined cases of the calculous and parenchymal groups, 7.6 per cent exhibited complete biliary obstruction. It may be emphasized that in 55 per cent of the cases of biliary tract cancer there was less than 1.0 mg. a day in contrast with but 1.7 per cent in the combined calculous and parenchymal groups.

3. The icterus index is usually higher in cancerous than in calculous jaundice, but there is sufficient overlapping to prevent reliability of any arbitrary dividing level in diagnosis. A wide range of the icterus index was noted in the cases of the parenchymal group. The intensity of icterus is dependent in part on the degree of biliary obstruction but may vary widely even if the latter is complete. This variation depends on the rate of blood destruction. Hemorrhage causes a decreased rate, with consequent reduction in intensity of jaundice.

4. Carcinomatosis of the liver may be divided into three groups with respect to icterus: (a) Discrete metastases with much relatively normal liver parenchyma and no involvement of the main hepatic ducts; there is little or no jaundice or urobilinogenuria. (b) Diffuse or confluent nodular metastases, with moderate jaundice, and urobilinogenuria; the clinical picture may simulate cirrhosis of the liver. (c) Metastases involving the main hepatic ducts, with deep jaundice and complete biliary obstruction; these cases are included with those of biliary tract cancer.

5. In 90 per cent of cases of biliary tract cancer there was less than 0.3 mg. of urobilinogen a day, while but 7 per cent of the combined calculous and parenchymal groups were in this range. Increases in the twenty-four hour urine urobilinogen were most frequent and marked in the parenchymal group but were often noted in calculous jaundice also. A number of other clinical features are of value in distinguishing these two groups of cases.

6. Jaundice due to traumatic common duct stricture may or may not be associated with complete biliary obstruction.

7. In two cases of chronic pancreatitis with jaundice, biliary obstruction was not complete.

8. The palpation of a nontender, smoothly distended gallbladder is strong evidence that jaundice is due to cancer. This may be regarded as certain if there is an associated complete biliary obstruction. The same type of palpable gallbladder is encountered rarely in the presence of incomplete biliary obstruction due to chronic pancreatitis.

THE SURGICAL TREATMENT OF LEAD ENCEPHALOPATHY

WITH PARTICULAR REFERENCE TO THE
PREVENTION OF SEQUELAE

W. TRACY HAVERFIELD, M.D.

PAUL C. BUCY, M.D.

AND

ANNA S. ELONEN, M.A.

CHICAGO

Lead encephalopathy as an entity was first described by Tanquerel des Planches,¹ although other forms of lead poisoning have been described by many other men whose names are well known in medical literature.² Since the work of Tanquerel des Planches many French clinicians³ have contributed to our knowledge of lead poisoning. The disease with its many forms and sequelae has also been recognized and studied in Australia,⁴ and Kato⁵ has recently summarized the extensive Japanese literature on the subject.

The sequelae of lead encephalopathy have included paralysis, tremor, hemiplegia,⁶ hallucination, paraplegias, amblyopia, hydrocephalus, convulsion, mental retardation, melancholia and delirium. These residuums have been observed predominantly in adults, though a few authors have considered the situation as it relates to children. In American pediatric literature Thomas and Blackfan⁷ were the first to point out that lead encephalopathy, while it did occur in adults, was much more frequent in children. Others⁸ have reported cases which have substantiated this premise. According to all reports the mortality in cases of lead encephalopathy in children has been very high. Blackfan⁴ published reports of four children who had convulsions, of whom three died and one recovered. This one was apparently well two years later. Strong⁹ had one patient who ate paint from the bed; meningeal signs with convulsions developed, and even though repeated lumbar punctures were performed the child died twelve days after the onset of symptoms. Aub and his associates² report a mortality of from 25 to 75 per cent. Of four patients observed by Park, Jackson and Kajdi,¹⁰ all had convulsions. Two died and the two that survived showed marked mental retardation. However, both of those who recovered had normal spinal fluid pressure during

the acute phase of the disease. In McKhann's¹¹ series of forty children with lead poisoning, twenty-four had symptoms of encephalopathy. Of these forty children nine died, and five of those who survived retained residuals. In another series McKhann and Vogt¹² reported forty-five cases of lead encephalopathy. Eleven patients died and twelve had permanent sequelae. Of these twelve four had convulsions and four had cerebral atrophy. Tremor was noted in two, six were mentally retarded, two had muscular weakness, three were blind and one had a speech defect. In 1926 McKhann¹³ reported the case of a child 23 months old who had lead encephalopathy and in whom a paresis of the left arm and leg persisted even after two years. Williams and his associates¹⁴ report forty cases in children in which lead poisoning resulted from using old storage batteries as fuel. Five patients had encephalopathy and there were no deaths. They say nothing of any sequelae developing.

It is obvious from a review of the literature that the reports concerning the sequelae of lead encephalopathy in children are few. Practically all of the older literature deals with adults, in whom the clinical picture is usually quite different. It is only in the last three decades that lead encephalopathy has been recognized as a not uncommon disease of childhood, which in the acute stage typically results in convulsions and in signs of meningeal irritation and of increased intracranial pressure. Even from the rather scant literature available it is, however, obvious that in general the mortality in this condition is high, varying from 25 to 75 per cent, and that the disease is particularly apt to prove fatal in children in whom convulsions and/or the signs of increased intracranial pressure develop. It is also apparent that complete and uncomplicated recovery from the disease is not as frequent as might be desired. Many of these children survive the acute episode only to be burdened with convulsions, mental retardation, blindness, paralysis or other manifestations of permanent injury to the nervous system for the rest of their lives.

Accordingly, we propose to review our few cases of lead encephalopathy in children in which the acute phase was promptly relieved by surgical decompression as reported by Bucy and Buchanan¹⁵ several years ago. We wished to determine whether this limited series might give us any clue as to whether surgical decompression is as successful in preventing the development of sequelae as it is in relieving the acute manifestations of this extraordinarily malignant and crippling disease of childhood.

It was McKhann¹¹ who first proposed a decompression for the relief of the increased intracranial pressure which so commonly occurs with lead encephalopathy in children. Roentgenograms of the skull had been taken only a few days apart in one of his cases of lead encephalopathy and revealed a separation of the cranial sutures. This "spontaneous decompression" resulted in a striking clinical improvement. As separation of the sutures is often inadequate he was led to advocate a surgical decompression in such cases. However, it would appear from his published works that this suggestion was never adopted in any of his

cases. Bucy and Buchanan,¹⁵ who first performed such a decompression as a result of an error in diagnosis, demonstrated the value of this procedure and advocated its adoption in suitable cases. In their cases the intracranial pressure was relieved and a rapid recovery ensued. These cases have now been followed, one for five years and the other for seven years after operation, and another case not previously reported at that time has been followed for three years after operation.

The case histories previously reported will be cited only briefly. A more detailed report can be obtained from the article by Bucy and Buchanan.¹⁵

REPORT OF CASES

CASE 1.—History.—Roy C., aged 2 years, was referred to the University of Chicago Clinics, where he was admitted Oct. 6, 1934, by Dr. Joseph Brennemann of the Children's Memorial Hospital. The history as given by the mother was that the patient and Ray, his brother, a fraternal twin, both ate painted plaster from the wall three months before admission. She gave them both castor oil, which Roy vomited but the brother retained. The brother immediately recovered but Roy soon became ill. From the onset until admission he had spells of vomiting of several days' duration between which he seemed to regain strength. The bowels were loose at times during this period. Six weeks before admission he had a generalized tonic

spasm lasting two minutes and on October 4 a clonic convulsion lasting one and a half hours.

Examination.—The head was enlarged and there was dilatation of the superficial veins of the scalp. There was a cracked pot sound on percussion. Ophthalmoscopic examination showed papilledema of from 2 to 2½ diopters. The pupils were equally dilated and reacted slowly to light through a small range. Nystagmus was absent and conjugate movements of the eyes were not restricted. The remaining cranial nerves were normal. The abdominal reflexes were absent. Sensation and muscular strength and coordination were intact. On walking and sitting the child showed some difficulty in maintaining his balance. There was glycosuria with a fasting blood sugar value of 138 mg. per hundred cubic centimeters, but the dextrose tolerance curve was normal. Roentgenograms of the skull showed a generalized diastasis of all sutures.

Diagnosis and Operation.—Since the history of eating paint was not obtained until over a month after admission, a diagnosis of malignant tumor of the midline of the cerebellum was made. A suboccipital craniectomy was performed. No tumor was found.

Postoperative Course.—October 17, x-ray films of the wrist showed a definite line of increased density at the distal end of the radius and ulna.¹⁶ Examination of the blood for stippling failed on all occasions to reveal any cells so affected. Lead was demonstrated in the spinal fluid, blood, urine and feces.

The patient's condition gradually improved, the papilledema subsided and the cerebrospinal fluid pressure soon returned to

normal. Since his discharge from the hospital he has been seen from time to time in the outpatient clinic with no more complaints and he has continued in excellent health. His optic disks are possibly a little paler than those of his twin brother. The visual acuity, however, has remained excellent.

The lines of increased density in the metaphyses of the long bones visible with the x-rays and diagnostic of lead poisoning in this case have been followed during the more than five years since the operation. With epiphyseal growth these lines have gradually moved farther and farther away from the epiphyses and at the same time have decreased in size until they are no longer visible in the x-ray films made in August 1939.

* Revised Stanford-Binet tests.

† Arthur performance scale.

Physically there has been a striking difference in the development of these fraternal (not identical) twins. Roy, the patient, has grown, as the accompanying chronological tabulation shows (table 1), to be much larger and stronger than his twin brother, Ray. He is the more aggressive of the two and invariably is the victor in any scuffle. However, it is noteworthy that even at birth Roy was considerably larger than Ray. Furthermore, the mother is certain that Roy was always the larger of the two boys, even prior to the operation. Unfortunately no records of their height or weight other than those recorded in table 1 have been kept.

Roy's mental development, however, has not kept pace with his physical growth and there is no question that he is retarded as compared with his brother, although he is by no means a feeble-minded child. He does not do as well in school, and his mother has often remarked that he does not comprehend as quickly as his brother. The intelligence quotients of both brothers have been obtained. The results are shown in table 2.

Psychometric studies on these twins have been interesting. On Jan. 7, 1938, these tests were given to the two boys separately. On the revised Stanford-Binet test Roy had a rating of 79 in contrast to Ray's 98. These tests were repeated Aug. 9, 1939, under the same conditions. Roy had a rating of 82, his twin brother of 106. August 17 by the Arthur performance test Roy obtained a rating of 88, his twin of 117.

In spite of the great difference in the twins' final results each time and on both forms, the same tendencies were noted originally and have continued to exist. On the whole they passed and failed the same general type of test, although Ray's initial level was higher and the range greater. Roy's performance was characterized by irregular scatter, marked perseveration, slow reactions, poor initiative and inability to note details. His speech has continued to develop more slowly than Ray's.

It would appear that lead encephalopathy has resulted in definite mental retardation in this case. The differences between the two boys of 19 and 24 points on the Stanford-Binet tests and of 29 on the Arthur performance tests are greater than one would expect in fraternal twins. Newman, Freeman and Holzinger in their book "Twins"¹⁷ give the range of differences for fraternal twins raised in the same environment as 1 to 40. According to these authors 32.7 per cent of such twins show differences of from 0 to 5 and 46.2 per cent of from 5 to 15 (table 3). Thus 78.9 per cent show differences of less than 15 points. It is obvious, therefore, that the difference ranging from 19 to 29 points present in these twins is far greater than one would expect

and is of a degree found in but few instances by Newman, Freeman and Holzinger (table 3). The disease has, however, resulted in no other permanent neurologic disorder and has obviously not retarded the boy's physical development, as Roy has continued to be taller, heavier and stronger than his twin brother, Ray.

The second case is also one of those previously reported by Bucy and Buchanan.¹⁵ It has not been possible to follow their third case.

CASE 2.—E. S., a girl aged 5 years, was referred to the University of Chicago Clinics by Dr. Joseph Brennemann, of Chicago. She was admitted on July 17, 1931, with the story that for the previous three weeks she had complained of headache and had been vomiting. The left eye had been turned in for one week. At first she vomited only once or twice a day, but for the week and a half before admission the vomiting had been more severe and she was unable to retain anything she ate. No nausea accompanied the vomiting attacks. The headaches were persistent for the three weeks period prior to admission, were not localized to any part of the head, but were generalized and varied in intensity from time to time. Four days prior to admission she complained of a stiff neck.

On examination there was a cracked pot sound on percussion of the skull. There were bilateral choking of the optic disks, paralysis of the left external rectus muscle and paresis of the right. There was no nystagmus. The pupils were regular and both reacted normally to light. Some decomposition of movements was present on the finger to nose test on the left side, with a general slowing of rapid alternating movements in both upper extremities. The deep tendon reflexes were hypo-active, and occasionally Babinski's sign could be elicited on both sides. She walked with her feet spread wide apart and with a staggering gait.

Roentgenograms of the skull revealed slight diastasis of the sutures and digital markings on the inner table of the skull, all pointing to increased intracranial tension.

Examination of the blood and urine revealed nothing abnormal.

A diagnosis of a midline cerebellar tumor was made, and July 23 a suboccipital craniectomy and cerebellar exploration were performed. No tumor was found. The unsatisfactory

diagnosis of "acute internal hydrocephalus of unknown origin" was made postoperatively.

The patient made a rapid uneventful recovery and was discharged from the hospital. Results of the examination at that time were normal except for slight pallor of both optic disks and paresis of the external rectus muscle of the left eye, which persisted for several weeks before the condition returned to normal.

After our experience with patient 1 in 1934, this patient was asked to return for reinvestigation because of the similarity between the two. On x-ray films of the wrist and knee taken Oct. 26, 1934, lines of increased density about 1 mm. wide and lying in the shafts of the long bones some little distance above the epiphyses were seen. On reviewing the films of the skull taken at the time of the acute illness in July 1931, it was found that a photograph of one shoulder was present on some of the films. A line of increased density was plainly

¹⁷ Newman, H. H.; Freeman, F. N., and Holzinger, K. J.: *Twins: A Study of Heredity and Environment*, Chicago, University of Chicago Press, 1937.

visible in the metaphysis of the humerus and had been overlooked at the original examination. Similar films made on Jan. 11, 1932, revealed the line slightly removed from the epiphysis.

Following her discharge from the hospital she was seen at intervals in the outpatient department. Except for an otitis media she continued to be well. She was last seen March 13, 1938, almost seven years after the acute lead encephalopathy and the decompression. She was then 12 years old. She was a bright alert child who had done well in her school work. General physical and neurologic examination gave no evidence that the disease had resulted in any permanent impairment. On the revised Stanford-Binet test an intelligence quotient of 96 was obtained. Her performance was characterized by an inability to recognize units as wholes and a tendency rather to be engrossed with detail; poor visual perception, and inconsistent performance in that she failed a simpler form of a given task yet would pass a more difficult version later on. The scatter was irregular.

Although, as Bucy and Buchanan¹⁵ pointed out, the diagnosis in this instance rests heavily on the roentgenographic observations as there was no direct demonstration of the presence of lead in the blood or cerebrospinal fluid or in any of the excreta, there can be little doubt of the accuracy of the diagnosis. The positive x-ray evidence as well as the typical acute development of the signs of increased intracranial pressure and the stiffness of the neck are all typical of this disease.

It is obvious that with the prompt relief of the increased intracranial tension by the surgical decompression she probably was spared the development of any of the neurologic or mental sequelae which so commonly appear in the wake of this disease.

At the time of their original report in 1935 Bucy and Buchanan¹⁵ remarked that, although through diagnostic error a suboccipital decompression had been made in their cases, they thought it not unlikely that the simpler subtemporal decompression would prove equally effective. We were soon presented with an opportunity to check this hypothesis:

CASE 3.—M. T., a girl aged 23½ months, was admitted to the University of Chicago Clinics Aug. 17, 1936, with a history of vomiting three or four times a week since the age of 11 months. This vomiting was associated with no other symptom, and usually occurred from right after to about one hour after meals. The severity of the vomiting was rather constant until about two weeks before admission, when it became worse, and for the week prior to admission she had vomited almost everything eaten. The vomiting was usually projectile in type. There was no other history of any gastrointestinal disturbances.

The child was fairly well developed and well nourished and was not particularly dehydrated. There was a suggestive Macewen's sign. The optic disks were swollen bilaterally 1 or 2 diopters. She walked with her feet wide apart, but neurologic and physical examinations were otherwise negative.

Roentgenograms of the wrists Aug. 22, 1936, revealed lines of increased density at the ends of the shafts of both bones of the forearm and the roentgenograms of the skull showed slight but definite separation of sutures. On examination of the blood, basophilic stippling of the erythrocytes was demonstrated. Glycosuria was present but the dextrose tolerance curve was normal (as in case 1). The red blood cells numbered 3,800,000 and the hemoglobin was 60 per cent. Further questioning of the parents elicited the information that the patient put many objects into her mouth and often chewed at her painted crib.

A diagnosis of lead encephalopathy was made and a right subtemporal decompression was performed on August 25. A needle was inserted into the lateral ventricle and a considerable quantity of clear colorless cerebrospinal fluid under considerable pressure was obtained. The defect in the temporal bone was enlarged, and a stellate incision was made in the dura mater.

The postoperative course was uneventful and she was discharged on the eighth postoperative day.

She was not seen again until Aug. 3, 1939, three years after the operation, at which time she was almost 5 years old. There were no complaints. The physical and neurologic examinations revealed only the site of the temporal decompression, which was flat and soft, and a questionable slight bilateral optic atrophy. The disk margins, however, were normal. She appeared perfectly normal in every other respect.

Roentgenograms of the skull showed the decompression and those of the long bones revealed the lead lines, which were diminished in thickness and density and were at some distance from the epiphyses.

When the patient was 4 years and 11 months old she was given the new Kuhlmann individual test. A mental age of 5 years with an intelligence quotient of 101 was obtained. Her speech and language development was superior to her ability to deal with numbers and her ability to control her motor coordination. She was a well poised and alert child.

Although the illness of this child was of a much more chronic nature than of the other two, it was also much less severe. Therefore, although it would appear that a subtemporal decompression is just as beneficial as a suboccipital one in relieving the acute manifestations of the disease and in preventing the development of sequelae, this cannot be definitely determined until this type of decompression has been tested in more severe cases.

During the same period of time two of our patients have died from this disease. Death of one patient may have been the result of an error in judgment as to the anesthetic agent used and we think it possible that he might have been saved. In the other case the disease was so severe and the child's condition so precarious at the time she was first seen that it is doubted whether any measures at that late date could have proved effective.

CASE 4.¹⁸—*Preoperative Course.*—T. M., a boy aged 21 months, was admitted to the University of Chicago Clinics Aug. 9, 1935. The parents stated that he had been well until one month previously, when he began to refuse food. He soon began to vomit. During this illness he had become constipated. He gradually lost weight and became disinterested and listless. A few days before admission he began to stagger when walking.

On admission the child appeared pale and listless. The pharynx was injected and the cervical lymph glands and spleen were enlarged and palpable. An ophthalmoscopic examination was apparently not made at that time.

The child became very restless and irritable. August 11 he had two generalized convulsions. The following morning at 4:30 he had another convulsion. The possibility of lead intoxication occurred to the attending physician, who then made careful inquiry concerning what the child had eaten. It developed that prior to the onset of the present illness the child had eaten some painted plaster and putty prepared with lead. Examination of the red blood cells revealed many stippled cells, and roentgenograms of the long bones revealed definite bands of increased density ("lead lines") in all the metaphyses. A lumbar puncture was made. The initial pressure was 350 mm. of fluid. The fluid was clear and colorless and contained 26 cells (23 polymorphonuclear leukocytes and 3 lymphocytes) and 62 mg. of protein.

We first saw the patient on the morning of August 12. At that time he was comatose, the temperature was 39.5 C. (103.1 F.), the pulse and respirations were irregular and he was having frequent convulsions. Percussion of the skull gave rise to a cracked pot sound; there were beginning papilledema in both eyes, moderate rigidity of the neck and extensor rigidity of all four extremities.

18. This case has previously been briefly referred to (case 2) by Cant, V. A.: Lead Poisoning: Exposures to Lead; Its Absorption, Transportation, Distribution and Deposition in the Tissues; Photometric Dithionite Method as Accurate Means of Determination; "Normal" Lead in Tissues and Urine, "Normal" Value in Blood, *Indust. Med.* 7: 608-622 (Oct.) 1938; Lead Poisoning: Fifty-One Fatal Cases of Suspected Lead Poisoning and Forty-Six of Nonfatal Lead Poisoning: Diagnosis; Treatment; Summary, *ibid.* 7: 679-699 (Nov.) 1938.

Diagnosis.—In view of these observations, the history of the ingestion of painted plaster and putty, the basophilic stippling of the erythrocytes and the lines of increased density in the roentgenograms, we concurred in the diagnosis of lead encephalopathy and advised an immediate decompression.

Operation.—Because of his poor condition it was thought best to perform the operation with local anesthesia. The subtemporal decompression was begun at 3:35 p. m. August 12. After the opening in the bone had been made and the dura mater incised, with relief of the increased intracranial pressure, a generalized convulsion suddenly developed and the patient ceased breathing. In spite of the administration of artificial respiration, stimulants and other remedies, spontaneous respiration was never resumed and cardiac activity ceased some fifteen to twenty minutes later.

Necropsy.—Microscopic examination of the brain revealed a moderate increase in the connective tissue of the leptomeninges and about the cerebral blood vessels, a moderate swelling of the capillary endothelium, a moderate number of gutter cells in the perivascular spaces, and severe degenerative changes in the ganglion cells of the cerebral cortex and the Purkinje cells of the cerebellum. In addition the necropsy revealed atelectasis of the upper lobes and hypostatic congestion of the bases of both lungs and fatty degeneration of the liver.

Chemical analyses performed in the laboratory of Dr. C. W. Muehlberger, coroner's chemist for Cook County, Ill., revealed 6.0 mg. of lead per hundred grams of bone, 6.0 mg. per hundred grams of liver and 0.51 mg. per hundred grams of cerebral tissue.¹⁹

Although this child's precarious condition makes it doubtful whether he could have survived under any circumstances, we cannot but question the wisdom of our having used a local anesthetic for a patient known to be suffering from frequent generalized convulsions. In retrospect it would seem wiser to have utilized a general anesthetic which would have prevented the development of the terminal convulsion which was, in all probability, the immediate cause of death.

CASE 5.²⁰—Preoperative Course.—A. M. R., a girl aged 7 years, referred to the University of Chicago Clinics by Dr. C. A. Elliott, of Chicago, was admitted Aug. 29, 1936. This child was well until three years previously, when she would at times lose her appetite for food and began to have spells of vomiting. Her mother stated that she had for four years had a most perverted appetite and that she frequently ate such material as sticks, dirt and paint from the stairs and woodwork. During this three year period she was always active and not confined to bed. Aug. 23, 1936, she again began to vomit, though more severely than previously. In the ensuing three days she was unable to take anything by mouth. August 27 she was admitted to the Woodlawn Hospital, Chicago, under the care of Dr. Elliott. She was in a semistuporous condition. There was rigidity of the neck, and Kernig's sign was present. Ophthalmoscopic examination revealed bilateral papilledema of 4 diopters, but no hemorrhages or exudates were seen. Examination of the blood revealed 4,710,000 erythrocytes, 16,150 leukocytes and 62 per cent hemoglobin. In the stained smear less than 5 per cent of the erythrocytes exhibited basophilic stippling. Roentgenograms of the long bones revealed typical lead lines of increased density in the metaphyses. In addition there were three other distinct lines of increased density somewhat removed from the epiphyses. These indicated that there had been at least three episodes of lead intoxication prior to the present one, the earliest two or three years previously.

Dr. Elliott, having made the diagnosis of lead encephalopathy, called us in consultation. We first saw her on August 29 and immediately transferred her to the University of Chicago Clinics for further care.

On admission she was stuporous but at times would cry out and move all four extremities. After the spells of crying,

respiratory movements would often cease for several seconds. The pulse was irregular, ranging from 50 to 60 per minute. She would move in response to painful stimuli. There was severe rigidity of the neck, and Kernig's sign was marked. The pupils were widely dilated and reacted sluggishly to light. There was an internal strabismus due apparently to a left external rectus palsy. There was a severe papilledema with optic atrophy.

Diagnosis.—It was obvious that this was an aggravated and chronic case of lead poisoning with a very severe encephalopathy and marked intracranial hypertension. She was taken directly to the operating room.

Operation.—A right subtemporal decompression was made on August 29 at 7:30 p. m. When first exposed the dura mater was under great tension and it could not be opened safely. The lateral ventricle was punctured but only a few drops of fluid could be obtained, owing, we believe, to compression of the ventricles by cerebral edema. (In other cases we had seen definite internal hydrocephalus.) Although 65 cc. of 15 per cent sodium chloride was administered intravenously, which reduced the tension somewhat, the temporal lobe herniated out of the dural opening in a most alarming fashion.

The pulse, which had been irregular and only 52 per minute at the beginning of the operation, was regular at 108 per minute at its close.

Postoperative Course.—After the operation the child's condition gradually grew poorer and she died at 7:40 p. m. September 3.

Necropsy.—A postmortem examination was made by the coroner's physician, Dr. Howard Zeitlin. He found beginning bilateral bronchopneumonia. There was severe cerebral edema. The right temporal lobe had herniated through the dural defect to a marked degree. There was also a definite pressure cone about the cerebellar tonsils and medulla oblongata. The lateral ventricles were very small. No localized lesions of the brain other than these were seen grossly.

Chemical analyses of the tissues made in Dr. C. W. Muehlberger's laboratory revealed 1.28 mg. of lead in 100 Gm. of liver, 0.99 mg. of lead in 100 Gm. of kidney and 1.91 mg. of lead in 100 Gm. of bone.

It is obvious that in this case we were dealing with a most aggravated acute exacerbation of a chronic condition. It appears doubtful, to us, if any form of therapy could have proved more effective.

CONCLUSIONS

We are well aware that no definite conclusions as to the prevention of sequelae can be drawn from three cases. Nevertheless they indicate that the acute manifestations of lead encephalopathy can be relieved by surgical decompression with a sparing of vision, endangered by the papilledema, and the preservation of life, and suggest that this same procedure may be beneficial in preventing the development of the common sequelae, such as mental retardation, paralyses and tremor. True, one of these three patients is somewhat below average mentally. But it must be borne in mind that of the three children who survived Roy (case 1) was the most seriously ill, had suffered from his disease for three months and was the only one to have convulsions. This, as well as the observations made in case 5, may indicate not only that surgical decompression should be done in these cases but that it should be done as early as possible. Delay may prove costly.

SUMMARY

Of five patients who had lead encephalopathy with the manifestations of increased intracranial tension two died. One might possibly have been saved had a general rather than a local anesthetic been used. The other was far too ill when first seen to have been benefited at that late date from any form of therapy. The three

19. The mean values for the tissues from a series of children not suffering from lead intoxication as reported by Gant²¹ are 0.182 \pm 0.053 mg. of lead in 100 Gm. of liver; 0.090 \pm 0.018 mg. of lead in 100 Gm. of kidney, and 1.335 \pm 0.561 mg. of lead in 100 Gm. of bone.

20. This case was previously referred to by Grant¹⁸ (case 6).

who survived have been followed since the operations for three, five and seven years. Two are perfectly normal physically, neurologically and mentally. One is physically in perfect health but is mentally somewhat below the average for his age and below his twin brother (not identical twin). However, he has surpassed his twin brother in physical development.

From observation of the cases and a review of the literature it is concluded that:

1. The development of the signs of increased intracranial pressure in a young child without definite localizing signs, especially when accompanied by convulsions or the manifestations of meningeal irritation or both, should suggest the possibility of lead encephalopathy. This condition can often be recognized by the presence of lines of increased density in the metaphyses of the long bones as demonstrated in the roentgenograms.

2. Surgical decompression of the brain is an effective means of relieving the symptoms of intracranial hypertension in such cases, of preserving life and vision and of preventing the development of sequelae if the treatment is not too long delayed.

3. General, not local, anesthesia should be used in operating in such cases.

4. It appears that either a suboccipital or a subtemporal decompression may be effective; which will be used must depend on the exigencies of the case.

THE OCULAR MANIFESTATIONS OF ARIBOFLAVINOSIS

A PROGRESS NOTE

In a recent communication we presented observations on ocular changes noted in a small group of patients with ariboflavinosis.¹ Slit lamp examination showed that a superficial vascularizing keratitis was the principal ocular manifestation. The corneal lesions and associated symptoms and signs disappeared during the administration of riboflavin and recurred when it was withdrawn.

The present report deals with observations made on forty-seven persons shown to be receiving insufficient riboflavin. Several presented no labial or lingual signs of ariboflavinosis but had definite ocular changes which resolved during treatment with the vitamin. The nine patients mentioned in our preliminary report are included in this series.

From the University of Georgia School of Medicine and the University Hospital.
Drs. A. P. Briggs, C. M. Templeton, A. R. Kelly and D. Eggleston aided us throughout this study.

In addition to funds supplied by the three organizations with which the authors are affiliated, facilities available to the University of Georgia School of Medicine from a grant-in-aid by the John and Mary R. Markle Foundation also were used in the study. (Dr. Sydenstricker is affiliated with the Department of Medicine, University of Georgia School of Medicine; Dr. Cleckley with the Department of Neuropsychiatry, University of Georgia School of Medicine, and Dr. Kruse with the Milbank Memorial Fund; Dr. Sebrell is a surgeon in the United States Public Health Service.)

1. Kruse, H. D.; Sydenstricker, V. P.; Sebrell, W. H., and Cleckley, H. M.: Ocular Manifestations of Ariboflavinosis, *Pub. Health Rep.* 55: 157 (Jan. 26) 1940.

SUBJECTS

The patients studied fell into three groups: Sixteen were hospitalized for nutritional disease, and of these eleven had pellagra or were known to have had typical pellagrous lesions within a year. Thirteen were outpatients; three of these were pellagrins in whom signs of ariboflavinosis developed during treatment with nicotinic acid. Eighteen were well nourished institutional employees provided with an apparently adequate diet; all but two of this group complained of cheilosis or of visual disturbances such as photophobia, dimness of vision or "eyestrain" not relieved by correction of refractive errors.

METHOD

Hospitalized patients were maintained on the basal diet deficient in all vitamins used in many previous experiments² and known to produce speedy relapse of pellagra when not supplemented with nicotinic acid. Signs of ariboflavinosis develop in from fourteen to thirty days after the addition of amounts of nicotinic acid sufficient to cure pellagra. (The term pellagra is used arbitrarily to designate the syndrome of glossitis and dermatitis, with or without psychic symptoms and diarrhea, specifically cured by nicotinic acid.) After an observation period of from five to seven days (except in cases 11 and 12, in which the condition was urgent) the predominant deficiency was treated with adequate doses of the appropriate vitamin. To avoid the effects of coincident deficiencies and precipitate the specific avitaminosis under study, the diet was supplemented by the daily administration of 20 mg. of thiamin chloride, 300 mg. of nicotinic acid, 50 mg. of ascorbic acid and 4 cc. of U. S. P. cod liver oil or 5,000 units of vitamin A. At times the dosage of various vitamins was increased to meet specific indications. After signs and symptoms of avitaminosis other than that of riboflavin had been controlled or when signs of ariboflavinosis developed in those patients being treated for predominant nicotinic acid deficiency (cases 3, 9, 10, 13), riboflavin was added. In seven instances (cases 3, 5, 7, 8, 13, 15, 51) treatment was discontinued after cure in order to observe relapse. In five (cases 3, 5, 7, 8, 51) repeated relapses were produced.

These patients were subjected to careful physical examinations with particular reference to disorders which might contribute to the development of nutritional deficiency. Neurologic and ophthalmoscopic examinations were made soon after admission. Erythrocytes, leukocytes, hemoglobin and cell volume were determined at weekly intervals. The concentration of vitamin A, nicotinic acid and ascorbic acid in the blood was estimated repeatedly in nine cases. The gastric contents after injection of histamine were examined each week. The lungs, heart and gastrointestinal tract were studied, often repeatedly, with the fluoroscope and roentgenograms. Electrocardiograms were made on admission and at intervals of a week. Tests for visual acuity and for dark adaptation were done repeatedly in ten cases. The eyes were examined with the slit lamp as soon as possible after admission and at intervals of two or three days thereafter.

Patients observed in the outpatient department were requested not to change their diets and to avoid taking yeast or cod liver oil except when prescribed. Physical examinations, blood counts, hemoglobin determinations and urinalyses were done. The eyes were inspected

2. Sydenstricker, V. P.; Schmidt, H. L., Jr.; Fulton, M. C.; New, J. S., and Geeslin, L. E.: Treatment of Pellagra with Nicotinic Acid, *South. M. J.* 31: 1155 (Aug.) 1938.

with the slit lamp once each week. The group of eighteen institutional employees (physicians, nurses and technicians) was of great interest, since they were all well nourished and active, with none considered ill. Three were on restricted diets, patient 17 on account of cholelithiasis, patient 21 because of quiescent peptic ulcer and patient 36 for the prevention of allergic manifestations. All were cooperative in making no changes in their dietary habits. Slit lamp examinations were made daily or every other day after the discovery of signs of ariboflavinosis.

dose was divided into three or five aliquots given at appropriate intervals to avoid loss from excretion.

The significant observations on these three groups of subjects are presented in table 1. No statistical importance can be attached to the incidence by race, sex or age of ariboflavinosis in these persons since the hospitalized patients were with one exception quite ill and suffering from multiple dietary deficiencies, the outpatient group was similarly complicated and the eighteen institutional subjects form a specialized group of white adults between the ages of 20 and 48, above

DOSAGE AND METHODS OF ADMINISTRATION OF RIBOFLAVIN³

When patients were hospitalized, the usual dose of riboflavin was 5 mg. daily administered in tablets or capsules containing 1 mg. In certain instances from 10 to 25 mg. daily was given in tablets containing 5 mg.; three patients were treated during certain periods with a solution of riboflavin in 65 per cent propylene glycol injected intramuscularly in amounts containing from 3 to 5 mg. of the vitamin daily. Ambulant patients took from 3 to 10 mg. daily in tablets or capsules. The daily

the average in physique and intelligence, with three exceptions free from known disease and with access to an adequate diet. The possible factors contributing to the development of an isolated avitaminosis in this latter group are the subject of present investigation. The incidence of symptoms and signs of ariboflavinosis in the forty-seven active cases is summarized in table 2.

OCULAR SYMPTOMS OF ARIBOFLAVINOSIS

Photophobia and dimness of vision not corrected by adjustment of refractive errors have been the most frequent symptoms in our patients. In those with severe conjunctival congestion and extensive corneal vascularization (patients 5, 8, 14, 24, 39) photophobia was extreme. Burning sensations of the eyeballs, "roughness" of the eyelids and extreme visual fatigue have

3. It should be noted that riboflavin undergoes rapid changes when exposed to light. All preparations of this vitamin should be well protected from light at all times. We have seen relapse occur in eight instances from failure to keep preparations of riboflavin used for treatment in a dark place.

been almost equally common. Nine patients showed marked impairment of visual acuity in the absence of refractive error or opacity of the media. The mild visual disorders often attributed to focal infection, toxic states and eyestrain have been conspicuously frequent.

Fig. 1.—Diagram indicating the grade of congestion and proliferation of the limbic plexus which was found to be the earliest sign of ariboflavinosis.

The earliest and most common sign of ariboflavinosis is circumcorneal injection; it was present in forty-five cases of the series. Often it was grossly visible, frequently it could be seen with a hand lens or ophthalmoscope, and always it was obvious on slit lamp inspection as marked congestion and proliferation of the limbic plexus. In cases not showing limbic congestion, arcus senilis and cataract were present. For reasons not apparent, the presence of arcus senilis would seem to offer some obstacle to the extension of capillaries beyond the sclerocorneal junction. The normal decrease in the number of vessels in the limbic plexus with age may be

an obvious explanation. Gross injection of the vessels of the fornix and sclera without evidence of infection but for convenience tabulated as "conjunctivitis" was seen in all but four of those cases presenting circumcorneal congestion. Actual invasion of the cornea by capillaries arising from the limbic plexus was observed thirty-seven times, and extensive patterns of empty vessels were seen in two patients recalled for inspection. Superficial nebulas, seen grossly as slight "steaminess" of the cornea and with the slit lamp as a fine diffuse superficial opacity, were present in eighteen instances,

and superficial punctate opacities were present in two cases. Interstitial nebulas were relatively uncommon, occurring only six times, while posterior punctate opacities were seen only four times.

As was noted in our preliminary report, the high incidence of circumcorneal congestion suggests involvement of the iris in ariboflavinosis. Frank iritis was seen in four cases of the present series, and moderate congestion of the iris with accumulation of pigment on its anterior surface was seen nineteen times. The latter condition, which is tabulated as pigmentation of the iris, was recognized to be abnormal only after accumulations and spots of pigment frequently had been seen to disappear during the administration of riboflavin. Mydriasis was striking in four patients; the incidence and behavior of mydriasis and of disturbances of accommodation will be the subject of a separate report. Cataract was observed in six of the group, all elderly persons. The possible relation of riboflavin deficiency to cataract in the human subject is under investigation.

THE PROCESS OF CORNEAL VASCULARIZATION

The earliest change which can be recognized with the slit lamp is marked proliferation and engorgement of the limbic plexus with the production of great numbers of very narrow capillary loops which outline the extreme margins of the scleral digitations and obliterate the normal narrow avascular zone between the plexus and the sclerocorneal junction (fig. 1). This condition can definitely be considered abnormal and possibly specific because it was seen in six patients with cheilosis (patients 16, 20, 21, 22, 27, 33), five of whom also complained of photophobia, and in three patients with photophobia but no cheilosis (patients 31, 35, 37). It was observed to progress to vascularization of the cornea within a week in the absence of treatment (patients 13, 20) and to regress rapidly during the administration of riboflavin to the other seven patients.

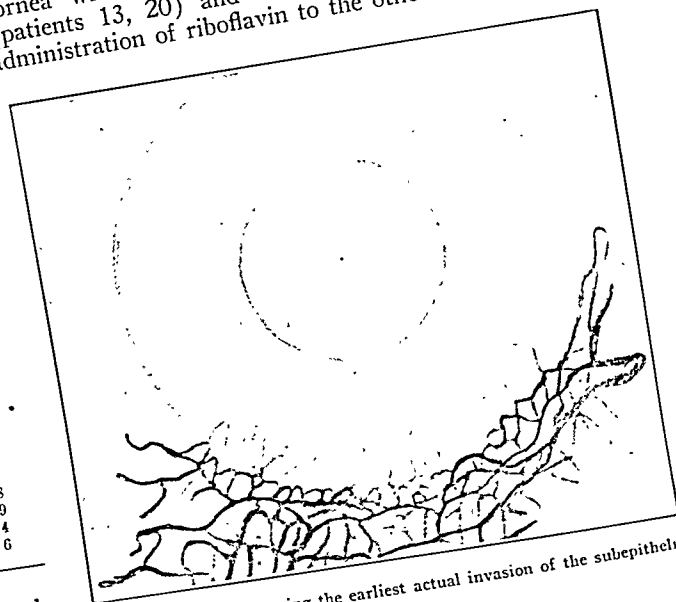

Fig. 2.—Diagram showing the earliest actual invasion of the subepithelial region of the cornea by capillaries.

The cornea is actually invaded first by very small capillaries arising from the apexes of loops surrounding the scleral digitations (fig. 2). These are most readily seen by retro-illumination and for optical reasons are most easily observed in the nasal and inferior quadrants of the cornea. Such capillaries lie just beneath the epithelium and soon anastomose to form a tier of loops from

which more single capillaries arise, extending centripetally. This process of anastomosis forms loops and projection of streamer-like capillaries from their apexes until extensive superficial vascularization is produced (figs. 3 and 4). Meanwhile, other penetrating vessels invade the substantia propria at varying depths. Much

Fig. 3.—The progress of corneal vascularization in ariboflavinosis.

later capillaries extend deeply to form a plexus just within the endothelium; this was observed in three instances (cases 5, 8, 13). Superficial and interstitial opacities were observed to develop at various stages of the vascularizing process; the deposition of posterior opacities was not observed. In cases of chronic relapsing ariboflavinosis (cases 5, 8, 13, 46) the cornea presented universal vascularization and extensive superficial and interstitial nebulas. The superficial plexus has always been more extensive and complicated than the posterior in contrast to the predominant posterior vascularization in interstitial keratitis attributed to syphilis (fig. 5).

RESPONSE OF OCULAR SYMPTOMS AND SIGNS TO THE ADMINISTRATION OF RIBOFLAVIN

Photophobia and burning and itching of the eyes have responded regularly within forty-eight hours to the administration of daily doses of from 5 to 15 mg. of riboflavin. The most spectacular improvement was in patients with extreme photophobia and blepharospasm (patients 5 and 8, figs. 6, 7, 8).

The moderate photophobia of many patients was entirely alleviated twenty-four hours after the ingestion of from 3 to 5 mg. of the vitamin. Since the dimness of vision was largely subjective, the degree of improvement has been difficult to evaluate; all patients with mild objective impairment of visual acuity were relieved. Among the hospitalized patients who had determinations of visual acuity, improvement varied from 5/200 before treatment and 25/30 afterward in case 8 to no improvement in 25/30 vision in case 9.

The resolution of keratitis during the administration of riboflavin was rapid. The initial proliferation and congestion of the limbic plexus have always shown notable regression within forty-eight hours after the ingestion of from 6 to 10 mg. of the vitamin. Almost complete emptying of the capillary loops on the scleral digitations, narrowing and "beading" of the limbic loops from which

they arose and definite narrowing of the small veins in the limbic plexus occurred with regularity. When invasion of the cornea had progressed only to the stage of straight streamer-like capillaries, complete emptying of the invading vessels was observed once after only 4 mg. of riboflavin had been ingested in twenty-four hours; ordinarily from 5 to 10 mg. during thirty-six to forty-eight hours was required. Blanching of the lips and tongue was coincident with the emptying of redundant corneal vessels. When vascularization was extensive the time required for emptying all vessels thought to be capillaries varied from five to eighteen days. In the three cases of chronic recurring keratitis (cases 5, 8, 13) a number of very large vessels were present which were never entirely empty of flowing blood though they were greatly reduced in caliber and the flow of blood was interrupted. In all instances the vessels remained visible as refractile or grayish streaks depending on the method of illumination used in inspection. Opacities did not clear in any direct relation to the emptying or apparent occlusion of newly formed vessels. In the same patient during different experimental periods the resolution of exudates has preceded and followed the emptying of capillaries by two or three days. Superficial opacities disappeared more slowly than interstitial nebulas, and posterior deposits were the last to clear.

In relapse produced by the withdrawal of riboflavin, photophobia was the first symptom to recur and always followed the reappearance of conjunctival injection; there was no direct relation to the reopening of corneal vessels (figs. 9 and 10). Impairment of visual acuity paralleled the objective signs of relapse in cases 5 and 8. Conjunctival injection was visible in from five to eight days after treatment was stopped. At the same time congestion of the limbic plexus with refilling of empty vascular channels could be seen with the slit

Fig. 4.—Further progress of corneal vascularization in ariboflavinosis.

lamp. With great regularity the superficial capillary plexus in the cornea reopened in from one to three days thereafter. Superficial and interstitial opacities became visible between the seventh and tenth days after withdrawal and tended to develop in the same regions of the cornea that had showed exudates before treatment. Cheilosis and glossitis seldom recurred before the end of the second week of experimental relapse.

The response of changes in the iris to the administration of riboflavin is the subject of continued investigation. In four cases of marked mydriasis (cases 22, 29, 36, 40) the pupils were greatly reduced in size and photophobia was much diminished after from three to five days of treatment. In nineteen cases (tables 1 and

Fig. 5 (case 8).—Advanced dietary keratitis; semidiagrammatic drawing indicating the degree of vascularization of the cornea in spontaneous ariboflavinosis of long duration.

2) it was thought that abnormal pigmentation of the iris was present and that this was associated with congestion of the iris. The great variations in the appearance of the normal iris were given due consideration. In gray eyed individuals there were pigment spots on the iris, and in the brown eyed the detail of the anterior surface of the iris was obscured by shaggy accumulations of pigment. During treatment with riboflavin the pigment spots on the gray irises disintegrated, leaving areas of yellowish discoloration; in some instances particles of pigment seemed to become detached and could be seen in the lower angle of the anterior chamber. The brown irises lost their shaggy texture and the details of crypts and contraction furrows became sharply defined. Iritis was present in cases 5, 6, 8 and 12, with posterior synechiae in cases 5, 6 and 12. Marked resolution of exudate was observed in cases 5, 8 and 12 during treatment with riboflavin.

REPORT OF CASES

The following case reports are illustrative:

CASE 13.—B. W., a Negress aged 25, was admitted Nov. 3, 1939, with the diagnoses of peripheral neuritis and pellagra. She was emaciated and febrile and had diarrhea with from eight to ten stools daily. There was pellagrous dermatitis of the hands, elbows and ankles. Cheilosis and seborrhea were absent; there was slight redness of the edges of the tongue with no papillary atrophy. There was general lymphadenopathy and slight splenomegaly. The rectum and vagina showed typical lesions of venereal lymphogranuloma. There were marked sensory and reflex changes and great motor weakness in all four extremities. The blood contained 4.6 Gm. of hemoglobin per hundred cubic centimeters and 2,100,000 erythrocytes and 9,000 leukocytes per cubic millimeter. Dextrose and nonprotein nitrogen values were within normal limits. The content of vitamin A was 0.051 mg. per hundred cubic centimeters. The Wassermann and Kahn reactions were strongly positive. The cerebrospinal fluid showed no abnormalities. The Mantoux test was negative, the Frei test strongly positive. There was gastric achlorhydria after injection of histamine. Electrocardiograms showed small amplitude of QRS complexes and small T waves in all

leads; there were no conduction disturbances. Slit lamp examination showed proliferation of the limbic plexus and slight anterior opacity of both corneas. Tests of visual acuity showed 15/30 for the right eye and 15/40 for the left eye. The patient was given the basal diet supplemented with 2 cc. of percomorph liver oil, 50 mg. of thiamin chloride intramuscularly, 500 mg. of nicotinic acid, 5 mg. of riboflavin and 50 mg. of ascorbic acid daily. Antisyphilitic treatment and treatment for venereal lymphogranuloma were instituted. By November 20 all signs of pellagra had disappeared and there was great improvement in the symptoms and signs of peripheral neuritis, so that the patient was able to feed herself and walk with assistance. Diarrhea with three stools daily persisted and was attributed to rectal lesions of venereal lymphogranuloma. No change in the appearance of the eyes was noted during this time. The daily dose of thiamin chloride was reduced to 15 mg. given by mouth. The experimental diet was discontinued and regular ward diet provided. The blood showed 0.14 mg. of vitamin A and 0.88 mg. of nicotinic acid per hundred cubic centimeters. On December 1 it was noted that there were many fine white comedones over the alae of the nose, that the buccal surface of the lips was red and that the tongue was purplish red with flattened papillae. Examination of the eyes with the slit lamp showed invasion of both corneas by capillary loops and sprouts and an interstitial nebula in the right eye with increase of anterior opacity in both eyes. By December 3 cheilosis had increased markedly and the patient complained of soreness of the tongue and photophobia; there was slight increase in the vascularization of the corneas. Riboflavin was increased to 10 mg. daily. Photophobia was absent on December 5 and there was slight decrease in limbic congestion. By December 8 cheilosis was healed, the tongue looked normal, limbic congestion was much less, approximately half the corneal vessels were empty and the interstitial opacity in the right cornea had disappeared. On December 13 the seborrheic lesions about the nose were healed, all corneal vessels were empty, the limbic plexuses looked normal and anterior opacities were much less marked. Visual acuity was 15/15 in each eye. On December 27 riboflavin was discontinued. Relapse occurred on January 14, 1940. Administration of 15 mg. of riboflavin daily was begun on January 21, with cure by January 26.

Fig. 6 (case 8).—Severe ariboflavinosis showing facial lesions, cheilosis and extreme photophobia with blepharospasm.

This patient developed lesions of ariboflavinosis while she was taking 5 mg. of riboflavin a day with other vitamin supplements sufficient to cure mild pellagra and severe peripheral neuritis; 10 mg. of riboflavin daily produced rapid cure of all signs and symptoms.

CASE 20.—E. A., a white woman aged 54, was admitted Jan. 13, 1940, complaining of weak eyes, sore mouth and tongue and pruritus vulvae resistant to local and endocrine treatment.

She was well developed and well nourished. There was marked photophobia with lacrimation, the conjunctivas were much injected and the pupils were large but reacted to light and in accommodation. Slight seborrhea of the forehead and malar eminences was noted. There were severe cheilosis and glossitis, typical of ariboflavinosis. Dermatitis of the exposed skin areas was absent. Results of the general physical examination were

Fig. 7 (case 8).—Appearance after four days' treatment with riboflavin. Facial lesions are healed with marked photophobia persisting.

not significant. There was fiery red dermatitis of the perineum and adjacent inner surfaces of the thighs; the introitus and vagina were fiery red with a serous discharge. There were no neurologic abnormalities. The blood contained 14.2 Gm. of hemoglobin per hundred cubic centimeters and 4,250,000 erythrocytes and 8,500 leukocytes per cubic millimeter. Dextrose and nonprotein nitrogen values were normal. The vitamin A content was 0.48 mg., nicotinic acid 0.19 mg. and ascorbic acid 0.7 mg. per hundred cubic centimeters. The Wassermann and Kahn reactions were negative. The cerebrospinal fluid was normal in all respects. The Mantoux and Frei reactions were negative. Values for the gastric acidity were free hydrochloric acid 17, total acidity 73. Electrocardiograms were normal. Examination of the eyes with the slit lamp showed marked congestion and proliferation of the limbic plexus with very numerous loops and sprouting capillaries invading the cornea superficially and extending centripetally for about one fourth its radius. There was moderate anterior opacity of both corneas and several interstitial nebulas were noted in both. The irises seemed normal. Visual acuity was 15/20, 15/20. The patient was given the basal diet supplemented by 4 cc. of U. S. P. cod liver oil, 20 mg. of thiamin chloride, 300 mg. of nicotinic acid and 50 mg. of ascorbic acid. During the ensuing six days there was no marked change in cheilosis, glossitis or the perineal lesions. Photophobia increased slightly and there was some increase in the number of corneal vessels. January 19 5 mg. of riboflavin was added to the daily treatment schedule. January 21 photophobia was much less, though there were no evident changes in the eyes on slit lamp examination. The pruritus vulvae was very much diminished and there was some fading of the redness of the introitus. On the following day there was very evident emptying of the corneal vessels and of the limbic plexus. By January 24 all vessels in the cornea were empty and there was much clearing of the interstitial nebulas. February 1 the limbic plexus looked normal, slight anterior opacity persisted but interstitial opacity was not visible anywhere. Visual acuity was 15/20, 15/20.

CASE 23.—A. R., a white woman aged 50, was seen as an outpatient on Jan. 3, 1940, complaining of soreness of the tongue and lips and photophobia. She also complained of progressive dimness of vision over a period of two years, not helped by frequent changes in her glasses, and of inability to write legibly on account of poor vision. The patient was intelligent, appeared

well educated and had no financial problems, but for a long while she had used a limited diet on account of "colitis." She was well developed and well nourished. Photophobia, lacrimation and slight blepharospasm were present, the conjunctivas were injected, and the pupils were large with normal reaction to light and in accommodation. Seborrhea was absent. There was severe cheilosis with deep painful fissures of the commissures, and the tongue was magenta with large flattened papillae. General physical examination showed slight enlargement of the heart and moderate hypertension. There were no abnormal neurologic features. The blood contained 13.5 Gm. of hemoglobin per hundred cubic centimeters and 4,500,000 erythrocytes and 5,200 leukocytes per cubic millimeter. Dextrose and nonprotein nitrogen values were not increased; the Wassermann and Kahn reactions were negative. Ophthalmoscopic examination showed slight pericorneal injection, moderate opacity of the media and normal optic disks; the retinal arteries were small and somewhat tortuous. Examination with the slit lamp showed great congestion and proliferation of the limbic plexus with very many capillaries invading the cornea superficially and extending over about one third its radius in each eye; there were no interstitial or deep vessels. There was diffuse anterior opacity with small punctate anterior deposits of both corneas. The architecture of the irises was clear but there were numerous brown pigment spots on both.

The patient was advised to continue her dietary habits and was given riboflavin 10 mg. daily. Seven days later she returned for observation. Photophobia and lacrimation were absent and the widening of the lid slits was striking; the conjunctivas were clear and the pupils much smaller. Cheilosis and glossitis were healed and she volunteered the information that her appetite was much improved. Examination with the slit lamp showed striking diminution in the size and number of the limbic vessels. All vessels in the corneas were empty and the superficial opacities had diminished about 50 per cent. The anterior punctate deposits were not changed. The pigment spots on the irises were reduced about 50 per cent in size. The dose of riboflavin was reduced to 5 mg. daily. Ten days later all opacities and deposits were absent, the limbic plexus looked normal, all corneal vessels remained empty though readily visible, and all pigment spots on the irises had disappeared, leaving yellow stains. The patient volunteered the information

Fig. 8 (case 8).—Cure of keratitis, facial lesions and cheilosis after ten days' treatment with riboflavin.

that she was able to read signs in show windows across the street for the first time in two years.

CASE 28.—J. B., a white man aged 30, examined on Jan. 23, 1940, because of slight photophobia, was sparely nourished but well developed. There was evident photophobia with narrowing of the lid slits and marked lacrimation during examination with the slit lamp. The conjunctivas were mildly congested; the pupils seemed normal. Cheilosis and glossitis were absent. Slit lamp inspection showed great congestion and

proliferation of the limbic plexus and extensive superficial vascularization of the corneas, with capillary loops and sprouts extending centripetally about one third of the radius. There was slight anterior opacity of both corneas. There was a large pigment spot on the nasal portion of the right iris, but the irises seemed otherwise normal. The patient was advised not to modify his diet and was given 5 mg. of riboflavin daily.

Fig. 9 (case 8).—Relapse on the ninth day following withdrawal of riboflavin, with extreme photophobia and blepharospasm. There was complete refilling of corneal vessels.

January 25 photophobia was markedly less and the lid slits were wider. The slit lamp showed that the limbic plexus was much less congested and that all the terminal sprouts and a great many of the invading loops in the corneas were empty; no change was evident in the anterior opacities but the pigment spot on the right iris was disintegrating. January 28, the fifth day of treatment, the limbic plexus looked normal. All vessels in the cornea were empty except two very large horizontally directed vessels on the nasal quadrant of the left cornea; the opacities were hardly visible and the pigment spot on the right iris had disappeared, leaving a slight yellowish stain. By February 2 all vessels in the cornea were empty and the opacities cleared. It was notable that the expression of the patient was changed by the absence of his habitual squint.

CASE 35.—D. E., a white man aged 24, examined on Feb. 2, 1940, had no complaints but was examined in the course of a survey of employees of an institution among whom signs of ariboflavinosis were extraordinarily frequent. Nutrition and development were excellent. There was evident photophobia with slight lacrimation, the conjunctivas were mildly injected and the pupils were wide. Cheilosis and glossitis were absent. Inspection with the slit lamp showed engorgement and proliferation of the limbic plexus in each eye with rather large capillary loops outlining the extreme periphery of each scleral digitation. Careful examination failed to show any vessels actually invading the cornea. There were no nebulas. There were several pigment spots on each iris but no evidence of exudates. Riboflavin, 3 mg. daily, was prescribed and the patient was advised against changes in diet. February 5 there was obvious absence of photophobia and lacrimation during examination. The vessels of the limbic plexus were much less prominent, many of the capillary loops outlining the scleral digitations were empty and in many others the flow of blood had stopped, though "beads" of trapped cells were visible. It was estimated that only about 25 per cent of these loops remained open. The pigment spots on the irises had diminished in size and density. February 9 photophobia was absent, the pupils were much smaller, the limbic plexus looked normal and all loops in the digitations of the sclera were empty; the pigment spots were represented by yellow stains with a few granules of pigment still adhering.

COMMENT

The observations on keratitis due to riboflavin deficiency recorded in our preliminary report have been considerably extended and evidence has been secured that certain changes in the iris as well may be a manifestation of this avitaminosis. Functional disturbances of vision out of proportion to visible changes in the cornea were present in a number of patients with oral and lingual as well as ocular lesions of ariboflavinosis. Ocular and oral lesions were observed during their development on a diet lacking in riboflavin but supplemented with adequate amounts of other vitamins. Similar lesions were seen in patients with definite histories of dietary deficiency. In a relatively large group of apparently normal persons with access to an adequate diet but complaining of functional ocular disturbances, mild keratitis and iritis were present but oral lesions were recognized in only one third. In every instance there were relief of functional disturbances and marked improvement or cure of visible anatomic lesions during the administration of riboflavin. In seven of the sixteen hospitalized patients and eleven of the thirty-one ambulant subjects, riboflavin was withheld after cure was apparently complete. Relapse occurred in every instance and cure was again obtained by the administration of the vitamin. Ocular symptoms and signs recurred quite regularly before cheilosis or glossitis was evident.

The incidence of ariboflavinosis as an apparently uncomplicated avitaminosis was surprisingly high in the present series. Fourteen of the patients had signs of pellagra or were known to have had them within a year. The remaining twenty-three had never had the symptoms or signs commonly associated with that syndrome. Gastrointestinal or biliary disease was present in only three instances. Bad dietary habits with inadequate intake of milk, eggs and green vegetables were prevalent in the entire group. It seems possible that

Fig. 10 (case 8).—Cure of relapse on the eleventh day of treatment with riboflavin.

other conditioning factors as yet undetermined may be potent in the production of ariboflavinosis.

The signs of human ariboflavinosis were first recognized by Sebrell and Butler⁴ in patients maintained on an experimental diet very low in riboflavin. Redness of the buccal surface of the lips, abnormal redness and

4. Sebrell, W. H., Jr., and Butler, R. E.: Riboflavin Deficiency in Man, *Public Health Rep.* 53: 2282 (Dec. 30) 1938; Riboflavin Deficiency in Man (Ariboflavinosis), *ibid.* 54: 2121 (Dec. 1) 1939.

desquamation of the vermilion areas, maceration of the commissures of the lips with subsequent fissuring and the production of rhagades were constant. Seborrhea of the nasolabial folds, alae nasi, eyelids and ears was frequent. Further observations have shown that seborrhea and follicular keratosis of the forehead, malar eminences and chin, the so-called "shark skin" eruption, are common. Very often there are fine filiform comedones over the cheeks and chin which simulate "urea frost." These lesions of the face and lips have long been considered signs of pellagra and have been described under various names.⁶ Subsequent clinical reports⁶ have confirmed the specificity of these signs for riboflavin deficiency. Recently a specific type of glossitis has been described.⁷ The tongue is clean, purplish red or magenta and frequently fissured. The papillae are large and flattened or mushroom shaped, giving the organ a coarsely granular texture. This type of glossitis is constantly present in patients with cheilosis and seborrheic lesions and may precede these manifestations. We frequently have seen it develop in pellagrins whose scarlet, denuded and atrophic tongues had become normal under treatment with nicotinic acid but whose diet remained deficient in riboflavin for several weeks. This glossitis has caused much confusion in the interpretation of the results of treatment of nicotinic acid deficiency since it has commonly been considered a sign of relapse of typical pellagra. Symptoms associated with the labial and lingual signs of ariboflavinosis are soreness of the lips and tongue, often with persistent burning paresthesia, pain on opening the mouth caused by stretching of the commissural fissures and sometimes dysphagia from tenderness of the tongue. Dermatitis, which is such a constant lesion in the ariboflavinosis of rats, has no definite parallel in human beings, though healing of dry scaling dermatitis of the hands and of universal seborrheic dermatitis has been observed during treatment with riboflavin.⁸

Several observers previously have noted ocular symptoms and signs in patients with the oral signs of ariboflavinosis.⁹ Spies, Vilter and Ashe¹⁰ noted impairment of vision, burning of the eyes, mydriasis and conjunctivitis in 70 per cent of one of their series of pellagrins. Though the symptoms and signs were suspected of being evidence of vitamin A deficiency, it was noted that a number of patients were relieved by the administration of riboflavin. Spies described similar symptoms in fifty cases of malnutrition which were relieved by the administration of oleum percomorpheum or carotene.

Pock-Steen¹¹ described conjunctival irritation, photophobia, dimness of vision, poor vision in dim light (aknephascopia), mydriasis, disturbances of accommodation and keratitis in 109 patients with sprue. These symptoms and signs were cured by riboflavin in seventy-eight instances. No report on the minute examination of the cornea and iris in human ariboflavinosis had appeared prior to our preliminary observations,¹ though the experimental background is unusually suggestive.

Goldberger and Lillie¹² in 1926 observed "ophthalmia," fissures at the angles of the mouth, glossitis and a specialized type of dermatitis in rats deprived of the heat stable fraction of yeast. Day and his collaborators,¹³ O'Brien¹⁴ and Bourne and Pyke¹⁵ have emphasized the incidence of cataract and of keratitis in rats maintained on a diet lacking in riboflavin. Day, Darby and Langston¹⁶ showed that these eye lesions could be prevented by the administration of "vitamin G," and Day and others noted that corneal opacities visible with the ophthalmoscope disappeared during treatment with riboflavin (vitamin G) but that cataract seemed to be an irreversible lesion. El Sadr¹⁷ also was able to cure all ocular lesions in rats except cataract with riboflavin after "ophthalmia" had been produced by a flavin deficient diet. O'Brien¹⁴ was able to arrest the progress of cataract at any stage by the administration of substances rich in riboflavin but did not report resolution of lenticular changes. Bessey and Wolbach¹⁸ and Eckardt and Johnson¹⁹ were unable to produce cataract in rats with any regularity by riboflavin deprivation, but both groups of observers noted the high incidence of keratitis in their animals. Bessey and Wolbach using the slit lamp in vivo and injection methods post mortem found that vascularization of the cornea was the earliest and most constant manifestation of riboflavin deficiency in the rat. Superficial and interstitial opacities occurred later from leukocytic infiltration of the epithelium and substantia propria. The newly formed vessels were rapidly occluded and exudates were absorbed after the administration of riboflavin. Lesions of the iris have not been noted in animal experiments, though O'Brien seems to have been the only investigator to mention the histologic appearance of this structure. This author also noted that mydriasis was an early sign of riboflavin deficiency in his animals.¹⁴

Our observations would indicate that there is a singular parallelism between the ocular lesions of

experimental ariboflavinosis in rats and those of the experimental and spontaneous avitaminosis in human subjects. All grades of corneal vascularization, curable with riboflavin, have been seen. Before actual invasion of the cornea by capillaries there is striking increase in the size and number of the vessels composing the limbic plexus, the capillaries are large and turgid and obviously increased in number, the normal narrow avascular zone between the limbic plexus and the sclerocorneal junction is replaced by a dense capillary network and each scleral digitation is outlined by a capillary loop. This appearance, which would not otherwise have been considered abnormal, was associated with ocular symptoms, particularly photophobia and burning and itching of the eyes, and it disappeared during the administration of riboflavin. It would seem that proliferation and congestion of the limbic plexus, often visible grossly as pericorneal injection, is the earliest sign of ariboflavinosis. In five of our cases this was true, though other signs were recognized later. Frequent examination with the slit lamp has shown that only a few days may elapse before actual invasion of the cornea by capillaries. Abnormal accumulation of pigment (probably of pigment bearing wandering cells) on the anterior surface of the iris has been striking in the majority of our early cases. The significance of this sign is not yet apparent, and we are not yet able to differentiate between "hazel spots" and pigment spots on the gray iris except by therapeutic test. The shaggy smoothed out appearance of the brown iris in ariboflavinosis is more easily recognized. In both types of irises there has been evidence of congestion of the iridic plexus in every instance of hyperpigmentation.

Many of our cases were in the early stages of keratitis and were not allowed to progress to the development of interstitial vascularization or of exudation. The relative incidence of signs and symptoms in tables 1 and 2 therefore represents various stages and the course of events in the progress of the condition rather than the variability of the pathologic condition at one stage. Particularly it should be noted that the more severe manifestations, such as exudates and opacities, have regularly appeared when riboflavin deprivation was allowed to continue. For the same reason superficial vascularization and opacity were more frequent than deep. The "dietary keratitis" always begins as a superficial or subepithelial vascularization of the cornea, superficial opacity is apt to follow, and later the invading vessels penetrate the substantia propria and are not apt to form a posterior plexus unless the deficiency is severe and prolonged. Interstitial nebulas may appear at any time after vascular invasion of the substantia propria; "posterior deposits" have been rare and occur only in the advanced cases with subendothelial vascularization. It is striking and probably significant that the vascularization of dietary keratitis is predominantly anterior while that of "syphilitic" keratitis is posterior. The late stages of the two conditions may be strikingly similar in appearance.

The functional disturbances of the eye associated with ariboflavinosis are of great interest. Photophobia, dimness of vision and ocular discomfort not improved after correction of refractive defects have been exceedingly common in our patients. Slit lamp examination has not failed to show some abnormality of the cornea or iris in patients complaining of these symptoms. The administration of riboflavin has caused prompt and sometimes dramatic relief of symptoms as well as resolution of

signs. When a slit lamp is not available it would seem justifiable to give riboflavin in adequate amounts to patients with such complaints as a therapeutic test. The questions of the possible relation of ariboflavinosis to such functional disturbances as spastic mydriasis and accommodation defect and such organic changes as cataract and iritis are important and will be the subjects of future reports. A possible relation of riboflavin to the function of vitamin A is suggested by the similarity of the visual disturbances attributed to the two vitamins.

The physiologic background for the production of ocular lesions by riboflavin deficiency has been presented by Bessey and Wolbach.¹⁷ Assuming that riboflavin is essential for the respiratory processes of all living cells, that normally it is ubiquitous and that the cornea respire only through its epithelial layer, the transfer of oxygen from the air to the deeper layers of the cornea must depend on the ability of the epithelium to transport it. Since riboflavin is apparently essential for the transportation of oxygen through the epithelium, when it is lacking asphyxia of the substantia propria results and vascularization of the cornea occurs as a compensatory process to bring blood in closer contact with the deeper layers.

SUMMARY AND CONCLUSIONS

Forty-seven patients with ocular symptoms and signs were cured by the administration of riboflavin. Examination with the slit lamp showed that proliferation and engorgement of the limbic plexus was the earliest lesion; this progressed to superficial vascularization of the cornea and the production of interstitial keratitis. Exudates were relatively infrequent but occurred in all the layers of the cornea.

Ocular symptoms were frequently those hitherto attributed to vague etiologic factors such as "toxic states," "focal infection" and "eye strain." Photophobia, dimness of vision and actual impairment of visual acuity were promptly, even dramatically, relieved by the administration of riboflavin, in some instances before visible changes occurred in the cornea.

Congestion of the sclera, vascularization and opacities of the cornea and abnormal pigmentation of the iris responded rapidly to the administration of riboflavin. When other signs of ariboflavinosis were present, they disappeared concurrently with the ocular lesions.

Ariboflavinosis is possibly the most prevalent apparently uncomplicated avitaminosis; it is possible also that it is more easily recognized than others on account of the specific lesions of the eye which occur early in the period of deficiency. The various factors contributing to clinical ariboflavinosis are not yet known.

Reference to Epilepsy in the Bible.—The first reference to epilepsy in the Bible is said to be the case of Balaam, the son of Beor, who fell into a trance with his eyes open and saw visions and heard the words of God. This has been described by certain of the older writers as a case of 'Furor a Dionysio.' . . . Other cases occur in the New Testament which are even more striking and characteristic. Such, for instance, is the case of Saul who, on the road to Damascus, had a definite optical aura, followed by a fall to the ground due to the commencing tonic spasm, and on partial recovery had hallucinations of the special senses and had to be led away in a condition of postepileptic stupor which lasted some three days, during which period he took no food. From this state he began to recover after the visit of Ananias, took food "and was strengthened" and slowly made a complete recovery.—Whitwell, J. R.: *Historical Notes on Psychiatry*, London, H. K. Lewis & Co., Ltd., 1936.

THE TREATMENT OF PREPUBERAL VULVOVAGINITIS WITH A NEW SYNTHETIC ESTROGEN

PRELIMINARY REPORT

JOSEPH D. RUSS, M.D.

AND

CONRAD G. COLLINS, M.D.

NEW ORLEANS

The first attempt to treat vulvovaginitis in infants and children with estrogenic biologic substance was in 1933, when Lewis¹ used it intramuscularly in eight cases. He succeeded in curing six cases. Subsequent attempts by others resulted in variable responses. Te Linde and Brawner² were successful in curing only one case in eleven, and Witherspoon³ failed to obtain any successful result in ten cases. On the other hand, Goldberg, Minier and Smith⁴ cured seven of nine cases and Limper and Hieronymus reported cures in twenty-four of their series of twenty-seven cases.

All these investigators used the biologic estrogens intramuscularly and in suppositories, because attempts

recommends the nightly use of a suppository containing from 600 to 1,000 international units. The duration of treatment varied from three to six weeks. In a previous study, one of us⁶ obtained similar results in a series of twenty-six cases. Equally good results were reported by Mayer.

Fig. 1.—Section of vaginal mucous membrane from patient with gonorrheal vulvovaginitis before institution of treatment, showing typical infant vaginal mucosa.

to administer them orally had been unsatisfactory. For example, Te Linde⁵ used them orally in doses of from 3,000 to 16,000 international units for periods of from sixty-nine to 123 days without success. British physicians also used daily doses of from 3,000 to 6,000 units orally with equally unfavorable results. The duration of their treatment varied from a few weeks to a few months.

Te Linde has shown that the vaginal administration of suppositories containing biologic estrogens is far more efficacious than either the oral or the hypodermic route. In a series of 175 cases all were cured. He

Fig. 2.—Section of vaginal mucous membrane from patient with gonorrheal vulvovaginitis five days after institution of treatment with diethylstilbestrol, showing marked adult type of mucosa.

These results prove the efficacy of the biologic estrogens in the treatment of prepuberal vulvovaginitis and indicate that thus far the vaginal mode of administration is superior to the intramuscular and oral routes.

DIETHYLSTILBESTROL

Dodds and his co-workers⁷ in 1938 introduced a new synthetic preparation, 4:4-dihydroxy-alpha:beta-diethyl stilbene, known to British investigators also simply as diethylstilbestrol. They claim that it possesses marked estrogenic properties. When standardized by the Allen-Doisy method, 1 mg. was found to have the same activity as 25,000 international units of estrone.

Fig. 3.—Section of vaginal mucous membrane from patient with gonorrheal vulvovaginitis seven days after cessation of treatment with diethylstilbestrol, showing adult type of mucosa and illustrating marked cornification.

Diethylstilbestrol has been proved to be an active estrogen in human beings as well as in experimental animals, and numerous reports of its use in adults confirm this.

Dr. Robert A. Strong, of the Department of Pediatrics, Tulane University of Louisiana, gave advice in the preparation of this article.

This study has been made possible by a grant from the Anonymous Research Fund of Tulane University and the Medical Research Division of Winthrop Chemical Company.

From the Department of Pediatrics and the Department of Gynecology, Tulane University of Louisiana School of Medicine, and the Hutchinson Memorial Clinic and Charity Hospital Clinic.

One of us (C. G. C.) used this substance intramuscularly in the treatment of menopausal symptoms in a series of fifty women and found it as efficacious as the biologic estrogens in controlling the unpleasant subjective symptoms manifested. In an additional fifty cases, in which we have used the drug orally for the same purpose, we have obtained similarly good results. It is apparently as effective orally as it is intramuscularly.

Studies on the toxicity of diethylstilbestrol indicate a broad margin of safety between the toxic and the effective dose for the laboratory animal. The intravenous lethal dose for the cat (the lowest for any animal tested) is 30 mg. per kilogram. We have not observed any toxic effects in patients to whom we have administered the drug. The only unpleasant symptom noted in our series of menopausal cases has been occasional nausea.

MATERIAL

Our material for this report consists of twenty-five cases of gonorrheal vulvovaginitis from the departments of pediatrics and gynecology of the Hutchinson Memorial Clinic and the Charity Hospital clinics. All cases

Fig. 4.—Smear of material taken from the vagina of an infant with gonorrheal vulvovaginitis, showing pus cells, gram-negative intracellular diplococci and an occasional immature nucleated epithelial cell.

were proved gonorrheal by smears stained by Gram's method and checked both by the pathology laboratories of Charity Hospital and by us. The youngest child treated was 20 months and the oldest was 12 years of age. There were six white and nineteen Negro children treated. The social service departments of Charity Hospital and the Hutchinson Memorial Clinic cooperated closely in having these patients keep their clinic appointments, and as a consequence opportunity was afforded us to keep a constant check on each case. Following the diagnosis and institution of treatment the patients reported weekly for three weeks, at which times smears were made and examined. Following three negative smears the patients were instructed to report at monthly intervals until two more consecutive negative smears were obtained. Thus when five consecutive negative smears were obtained the patient was discharged.

METHOD AND RESULTS

On diagnosis of gonorrheal vulvovaginitis the child, irrespective of age, weight, duration of symptoms or previous therapy, was given a 1 mg. tablet of diethylstilbestrol three times a day until twenty had been taken. The tablet was crushed and administered in 2 ounces (60 cc.) of milk. The usual prophylactic

methods and instructions were given to the mother, but the only form of treatment given was orally administered diethylstilbestrol. In twenty-two cases negative smears for pus and gonococci were obtained at the end of seven days of treatment. Two cases required nine days of treatment (27 mg.) and eighteen days of treat-

Fig. 5.—Smear of material taken from the vagina of an infant with gonorrheal vulvovaginitis five days after treatment with diethylstilbestrol, showing very large cornified epithelial cells with pyknotic nuclei. Pus cells and gram-negative diplococci have completely disappeared.

ment (54 mg.) respectively to produce a cure. The smear then showed only large cornified epithelial cells, some with pyknotic nuclei and mucus. We have noticed the same condition in vaginal smears from patients with senile vaginitis whom we have treated with stilbestrol.

Within seventy-two to ninety-six hours the discharge changes in character, becoming thin, mucoid and white. The latter type of discharge persists throughout treatment, and complete disappearance of any type of discharge is noted within one or two weeks after discontinuance of treatment. The thick greenish yellow discharge definitely diminishes in amount within thirty-six to forty-eight hours.

Fig. 6.—Smear of material taken from the vagina of an infant with gonorrheal vulvovaginitis fourteen days after cessation of treatment with diethylstilbestrol, showing cornified epithelial cells, immature epithelial cells and a large number of Doederlein and lactic acid bacilli. No pus cells or gram-negative intracellular diplococci are seen.

In the first few cases treated some nausea and vomiting were noted, but these symptoms have not been observed since we have administered the drug in milk. In no case did vaginal bleeding occur. In approximately two thirds of the cases a darkening of the nipple and areola occurred, together with slight painless enlarge-

HISTAMINASE IN THE TREATMENT
OF HAY FEVEREDMUND L. KEENEY, M.D.
BALTIMORE

ment of the breasts. In several cases pigmentation and painless enlargement of the vulva also was noted. In all cases these symptoms disappeared within three weeks of discontinuance of the drug.

We have observed eight of these cases for three months after discontinuance of therapy and there have been no recurrences in any of them. Seven cases have been observed for from two to three months. In the latter group two reinfections have occurred; in both cases a positive smear was obtained following two negative smears. Thorough investigation revealed that the two children slept in the same bed with a sister who proved to have gonorrheal vaginitis. Both patients were retreated with 20 mg. of stilbestrol and negative smears were obtained at the end of seven days. Both patients have had three negative smears following the second course of treatment. Their sisters also responded to therapy and are included in this series. Ten cases have

been followed for from two weeks to two months after the discontinuance of therapy, and as yet there has been no evidence of recurrence.

COMMENT AND CONCLUSIONS

At the present time we are enthusiastic about the use and efficacy of diethylstilbestrol orally in the treatment of infant vulvovaginitis. The fact that this synthetic estrogen can be taken orally in milk eliminates the possibilities of the child's knowing that she is taking a drug as well as becoming "genital conscious," as might be the case when suppositories are used. Furthermore, the rapidity of cure, the absence of toxic or deleterious effects and the ease of administration as regards both the family and the physician lead us to believe that it is an ideal drug for the treatment of vulvovaginitis. The fact that diethylstilbestrol is synthetic and is required for such a short period makes it an economical method of treatment as compared to all previous biologic hormones.

Medical Arts Building.

Best¹ demonstrated, from the results of in vitro experiments, that a histamine inactivating substance existed. Later Best and McHenry² proved the specificity of this inactivating substance for histamine and accordingly suggested that the inactivating substance be known as histaminase. Histaminase has now become a popular drug for clinical experimentation in allergic diseases and allied disorders. The foundation for this clinical experimentation is based entirely on the hypothetical assumption that the allergic reaction is caused by the liberation of "H-substance" at the site of contact of antibody with antigen and on the probability that histaminase might inactivate the "H-substance," which is similar but not identical to histamine. Histaminase has been reported to be effective in the treatment of hay fever,³ urticaria,⁴ angioneurotic edema,⁵ allergic eczema,⁶ seborrheic eczema,⁷ acne vulgaris,⁷ Ménière's disease,⁸ gastrointestinal allergy,⁸ ulcerative colitis,⁹ cold allergy¹⁰ and serum sickness.¹¹ Recently histaminase (Winthrop) has been made commercially available and has been widely advertised as a drug effective in the treatment of allergic diseases.

It is extremely difficult to establish satisfactory evidence for the effectiveness of therapeutic agents in any of the so-called allergic diseases. This is due in part to the difficulty in determining the exact etiologic factors. Even when these factors can be determined they cannot always be controlled sufficiently to permit the formulation of satisfactory conclusions.

Seasonal hay fever is a typical disease of allergy and its etiology can be specifically determined. Furthermore, the symptoms of hay fever are in direct proportion to the amount of pollen in the atmosphere. The pollen concentration of the atmosphere can be easily determined by exposing specially prepared slides in various locations and counting the number of pollen grains in a measured area on the slides. Therefore the effectiveness of specific therapy in hay fever patients can be accurately determined by comparing the daily symptomatology records with the daily pollen counts. Since histaminase is advocated as a drug effective in controlling disorders of an allergic nature, it seemed by its use in the treatment of patients with seasonal hay fever. Furthermore, since its effectiveness is sup-

posedly due to its ability to inactivate histamine, it seemed important to observe, simultaneously, the effect of histaminase on the histamine reaction.

Fifteen patients known to have typical symptoms of hay fever beginning about the middle of August and lasting until the first frost were chosen for study. Each patient gave a typical positive intradermal reaction to a weak dilution of both giant and short ragweed extract. On Aug. 10, 1939, a record of daily pollen counts was started and was continued throughout the entire ragweed hay fever season. On August 23 the pollen concentration reached a height sufficient to produce typical symptoms of hay fever in all fifteen patients. Histaminase therapy was immediately begun and a daily symptom record was started for each patient. The histaminase was administered orally. The patients were first instructed to take 45 units of histaminase daily, but later the dose for six of the patients was increased to 60 and 75 units a day. After two days of treatment each patient reported improvement. However, the improvement could be accounted for by a sudden drop in the pollen counts following a heavy rainfall. Subsequently, with a rise in the pollen count the hay fever symptoms of all the patients reappeared and continued to become more severe as the pollen concentration continued to increase. Observations were conducted for a period of from ten to twenty-one days. All the patients continued to have hay fever during the course of study and any fluctuation in the symptoms that occurred was accounted for by a concomitant fluctuation in the pollen concentration of the atmosphere.

Before the onset of hay fever symptoms and, therefore, before the onset of histaminase therapy, each patient was tested intradermally with 0.001 mg., 0.0001 mg. and 0.00001 mg. of histamine acid phosphate. By this titration of the histamine tests, it was hoped to determine the smallest amount of histamine to which each patient would react. Any subsequent alteration in the cutaneous reaction that might occur as a result of histaminase therapy could then be accurately ascertained. The size of the reaction, i. e. the wheal and the erythema, was measured ten minutes after the test was made, and it was found that the greatest reactions occurred at the site of the largest doses. All the patients reacted to 0.001 mg. and 0.0001 mg., whereas only seven of the patients reacted to 0.00001 mg. of histamine acid phosphate. On the day histaminase therapy was terminated the histamine tests were repeated, and the results were compared with those previously noted. No appreciable change in the histamine reaction was observed in any of the fifteen patients.

SUMMARY

Histaminase was administered orally to fifteen patients with typical ragweed hay fever during the height of the 1939 ragweed season. Daily pollen counts were made and a daily symptom record was kept for each patient. Titrated intradermal tests with histamine acid phosphate were made before and after histaminase therapy.

Histaminase failed to give relief to any of the patients with ragweed hay fever. Any fluctuation in symptomatology that occurred could be accounted for by a concomitant fluctuation in the pollen concentration of the atmosphere.

Histaminase therapy did not alter the histamine reaction of any of the fifteen patients.

Clinical Notes, Suggestions and New Instruments

THE HOT DOUCHE

C. A. ANDERSON, M.D., BURLINGTON, N. C.

For some time I have used a method of applying heat in the treatment of such conditions as chronic pelvic infections and salpingitis which has proved most satisfactory. Probably some one can get a suggestion from the description of my method and render the hot douche more popular.

For a disease which requires months of daily treatments, office instruments for applying dry heat in the vagina are barely practicable for the wealthy and not practicable for the nullipara, and the cost renders these treatments prohibitive for the poor. Furthermore, the hot douche, although inexpensive, is probably a better method of conveying heat to the pelvic organs.

Maintaining the necessary uniform high temperature of the douche for from thirty to forty-five minutes I found impracticable, almost impossible, until I thought of controlling the flow with a Hoffman clamp. Now I use boiling water in the fountain syringe bag and close the clamp until the water cools in the tube and escapes from the vaginal tip at the desired temperature. If the douche is too hot, a slight turn of the clamp corrects it; if it is too cool, a slight release of the clamp raises

Materials for hot douche.

the temperature. I depend on the patient's feeling as to what temperature she can stand. Within a short time she begins stepping up the temperature. My patients tell me that one bag, or half a gallon, of boiling water lasts for from forty to fifty minutes.

Some of my failures have impressed on me the necessity of giving fully written instructions. I now read my patient type-written instructions, explain them to her and let her take a copy similar to the ones here given. The simple little clamp solved a difficult problem.

WRITTEN INSTRUCTIONS FOR THE HOT DOUCHE

The prolonged hot douche is one of the more useful local treatments in diseases of women.

In certain cases it is very beneficial when properly taken. When not properly taken it may do serious damage.

FOLLOW DIRECTIONS CLOSELY

Water
Add

For the first few days, while learning to control the flow, use water as warm as you can bear without scalding.

After you learn to control the flow, the temperature of the water in the bag may be gradually stepped up to boiling and allowed to cool in the tube to the desired temperature while it slowly trickles into the vagina.

Close the clamp until the water runs slowly and bend tubing when you wish to stop the flow.

Should the water in the tubing cool too much, a slight release of the clamp will raise the douche temperature.

Don't use water too hot until you learn to control the flow to a slow trickle.

It is heat and not the quantity of water that is desired.

The douche must last for from thirty to forty-five minutes.

If the douche is uncomfortable or painful, stop using it until you see your doctor.

DANGER!—Use vaginal tube with holes in the side. The tube with a hole in the end (rectal tube) may cause serious trouble.

CECOSTOMY—SWENSON

Jour. A. M. A.
JUNE 22, 1940

The bag should not be more than 2 to 3 feet above your body.
There are different modes of taking a douche. Use the mode you like.

1. Lie in the bath tub if the bathroom is not too cold in the winter or too hot and stuffy in the summer.
2. Lie in bed with douche pan—if you can do it without spilling water on the bed.
3. Place slop jar beside bed, a chair on each side of it and a box on each chair if necessary to raise to bed level, a hard pillow 6 inches from edge of bed, a piece of oilcloth (not rubber) over pillow and down into slop jar, the lower end having been rolled and fastened with a safety pin, forming a conical spout. The douche bag filled, the patient pulls up gown, sits down, falls back with the pillow under the small of her back, places her feet on the boxes and if the room is cold wraps her limbs. The water drops into the oilcloth cone. Warm water should be used in the bag, until one gets the knack of controlling the flow by using the clamp and bending the tubing.

DOUCHE

Water.
Prescription:

Heat. If douche temperature falls, a slight release of clamp will raise the temperature.
Bag not more than 2 to 3 feet above your body.
Use vaginal tip.
Time, thirty to forty-five minutes.
The daily paper or a magazine helps to pass the time.

A NEW INSTRUMENT FOR SAFELY DECOMPRESSING THE CECUM DURING CECOSTOMY

ORVAR SWENSON, M.D., BOSTON

This new intestinal aspirator is designed to avoid the usual difficulties encountered when decompressing the obstructed colon prior to performing a cecostomy. If partial deflation can be done readily and safely, it often permits easy manipulation of the cecum and facilitates subsequent operative technic. If such drainage is attempted with a trocar, the instrument may

Fig. 1.—Schematic drawing of the new instrument.

become occluded before sufficient decompression is accomplished. When this occurs, removal of the trocar is necessary, with subsequent welling out of intestinal contents. Furthermore, insertion of a large trocar through a tense, thinned out intestinal wall may cause the bowel wall to split, permitting fecal material to ooze around the trocar.

The instrument consists of a large double wall tube so arranged that, when negative pressure is applied, the space between the two walls acts as a suction cup and virtually seals the instrument to the viscus. The suction cup, as well as the large inner tube through which drainage takes place, is shown in the schematic drawing (fig. 1). Two suction lines are attached to the instrument: one is connected to the suction chamber which holds the instrument in place and the other to the inner aspirating tube through which evacuation takes place. A removable metal cap (shown in figure 2), equipped with a rubber diaphragm, facilitates cleaning. The rubber diaphragm illustrated in figure 3 enables retraction of the Bard-Parker

From the Surgical Clinic of the Peter Bent Brigham Hospital.
Suggestions and help were given by Drs. F. C. Newton and Carl Walter and Mr. K. B. Smith aided in the mechanical construction of the instrument.

knife (No. 7) within the aspirating chamber during the application of the instrument, as well as its manipulation in opening the intestine. This illustration also shows the perforated metal disk within the suction chamber, which prevents excessive invagination of the intestinal wall. This stabilizes the instrument during deflation and minimizes trauma to the bowel wall.

Fig. 2.—Removable metal cap which facilitates cleaning the instrument and knife in place.

In figure 4 the instrument is assembled with the metal cap for drainage; suction is applied first to the suction chamber until the blade perforates the intestinal wall. The intestinal contents are evacuated through the central tube and passed out one side arm, negative pressure being applied if necessary. When the instrument is in place, considerable traction can be applied without dislodging it. Hence it can be used to draw the intestine out of the incision and obviates the use of traumatizing clamps.

Fig. 3.—Rubber diaphragm and perforated metal disk within the suction chamber.

After adequate decompression and the delivery of the cecum through the incision, purse-string sutures are placed round the instrument before the latter is removed by relieving the suction. The surgical procedure of choice can be performed from this point on. A negative pressure of from 10 to 15 inches of water is adequate for the efficient operation of the instrument.

Fig. 4.—The assembled instrument.

There are other conditions necessitating drainage in which this evacuator can be used to advantage. Benign, malignant and parasitic cysts can be drained with this closed system. Markedly distended gallbladders can be drained. The proximal loop of distended intestine in intestinal atresia of the newborn obstruction. can be decompressed in the manner described for intestinal

PEDUNCULATED FIBROLIPOMA OF THE VULVA

GEORGE DE TARNOWSKY, M.D., CHICAGO

While fibromas or fibrolipomas of the vulva are only comparatively rare and their removal presents a rather simple problem in plastic surgery, the following case seems worthy of report:

REPORT OF CASE

History.—Miss R. A. aged 21 was referred to me by Dr. A. J. Schwartz, Nov. 16, 1939, for the removal of a pedunculated tumor arising from the right labium majus. Some two years before the patient—unusually shy and modest—had begun to notice that she was—to quote her own words—"getting fat between her thighs." She gave up swimming on this account but otherwise continued her social and athletic activities, including dancing. The tumor continued to grow and elongate until it reached half-way down her thigh. Some two months prior to her hospital admission the lower margin of the tumor began to ulcerate. This so alarmed the patient that, for the first time, she confided in her mother and allowed the latter to examine her external genitalia.

On examination a pedunculated tumor, 32 cm. long, with an ulcerated apex, was disclosed. The mucosa of the right labium majus was dragged down a distance of 10 cm. The upper half of the pedicle was lymphedematous while the lower portion gave one a doughy feeling suggesting a lipoma rather than a soft fibroma. Three ulcerated areas bled easily on palpation. No other anomalies were noted; routine laboratory reports were all negative.

Under cyclopropane anesthesia the right labium majus was restored to its normal size and shape. The mucosa was dissected free from the tumor and a sufficient flap of skin left for plastic repair prior to removal of the entire pedicle.

Pathologic Report.—The tumor was large, soft and pedunculated and weighed 1,270 Gm. It measured 21 by 17 by 7 cm. Over its apex were three ulcerated areas from 1 to 3 cm. in diameter. Microscopically the central portion of the tumor was made up of both fibrous and fatty tissues. Lymphedema was present throughout the proximal half of the mass. Some areas were very cellular but no definite evidence of sarcoma was noted.

During the past month two similar but sessile vulvar fibromas have come to our service. A woman aged 60 who was sent to the hospital for removal of a carcinoma of the fundus uteri had a tumor of the left labium majus the size of a large grapefruit which, she stated, was congenital. Her married daughter had a similar growth on her right labium majus.

30 North Michigan Avenue.

Case presented before the Chicago Gynecological Society, Jan. 19, 1940.

Fig. 1.—Pedunculated fibrolipoma of the vulva.

Fig. 2.—Appearance immediately after removal of tumor.

Special Article

CONFERENCES ON THERAPY

THE TREATMENT OF BLOOD DISORDERS

IV. ROENTGEN THERAPY

NOTE.—These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with the collaboration of other departments. The questions and discussions involve participation by members of the staff of the college and hospital, students and visitors.

DR. PAUL REZNIKOFF: Dr. Forkner starts the discussion this morning on the use of roentgen therapy in disorders of the blood and blood-forming organs.

DR. CLAUDE E. FORKNER: There are only a few diseases of the blood in which x-rays are used for treatment. Among these are leukemia, the lymphoblastoma group of diseases including Hodgkin's disease, lymphosarcoma, reticulum cell sarcoma, small round cell sarcoma, and polycythemia. The thrombocytopenic purpuras and granulocytopenia will be discussed briefly, but I feel that roentgen treatment as a rule is not indicated for either of these.

A variety of x-ray technics has been applied in the treatment of leukemia. Nicholas Senn, when he first found that x-rays were effective in leukemia in 1903, thought that he had cured the disease. He used a crude apparatus. Since that time many voltages have been used, varying from a very few kilovolts to over 1,000 kilovolts. Filters of a dozen different sorts and thicknesses have been used. Skin focus distances ranging from a few centimeters to several meters have been employed, and sizes of fields of irradiation from a few square centimeters to that of the total body surface. Varying milliamperages have been used. With all these, good results have been obtained, but I think perhaps not very much better results than was the case in the original method of Senn with a crude apparatus. In leukemia it is paradoxical that the disease is most effectively treated by agents which are known experimentally to induce the disease. The agents are arsenic, x-rays, radium and benzene (benzol). All may be effective in bringing about a more easily transmissible leukemia. In animals they may actually induce a higher incidence of leukemia than occurs in control groups. There is a good deal of evidence that even in man irradiation in some cases is a factor in inducing leukemia. That may be the reason why leukemia cannot be cured with any of these agents—because the agents used to cure the disease also tend to make the patient more susceptible.

What are the indications for the use of x-rays or radium for patients with leukemia or with one of the lymphoblastoma group of diseases? First one must view the whole patient. A high leukocyte count, the presence of an enlarged spleen, enlarged lymph nodes or any other single factor should not be considered alone in the decision as to whether or not the patient needs treatment. The occurrence of symptoms is especially important as pointing to the need for treatment. There often are general symptoms such as fatigue, low grade fever and loss of weight. Symptoms are sometimes brought about by the enlarged organs, such as enlarged lymph nodes, perhaps in the mediastinum, or a large spleen producing pain, a dragging sensation or per-

haps gastrointestinal disturbances. Symptoms may be brought about by the increased metabolic rate, such as excessive perspiration, rapid loss of weight and fatigue. There may be symptoms due to progressive anemia, which may at times be severe, or a rapidly increasing white blood cell count with increasing numbers of immature cells. All of these may point toward the probability that the patient may need specific treatment with x-rays, radium or some other agent, whichever you choose. At times itching, particularly in the lymphogenous group of leukemias, even though the patient may be well in other respects, may indicate treatment. Patients can go along with a leukocyte count of 100,000 or 200,000 per cubic millimeter for long periods of time and still feel quite well. We use treatment in leukemia as a palliative measure, knowing well that no cure can be accomplished. Since x-rays are a palliative measure they should not be employed when the patient is without symptoms. However, at times one can anticipate that a patient will have symptoms in the near future, and then one may forestall an imminent relapse.

It is important also to know the indications for stopping treatment in disorders such as leukemia and lymphoblastoma. It happens too frequently that patients are overtreated with x-rays and radium. Perhaps the best treatment is that which will bring about satisfactory recession of symptoms and nothing more than that; in other words, the least treatment which is effective in relieving the symptoms is the proper treatment in leukemia; this applies also in the lymphoblastoma group of diseases. Some patients are extraordinarily sensitive to x-rays or radium; others are more resistant, so that one should at first treat the patient cautiously and observe the reaction. Some patients exhibit a delayed effect and several weeks may pass before the maximum effect occurs. If one does not allow for this, one may obviously overtreat the patient. It is important to observe the symptoms during the initial series of treatments. These may serve as a guide to how that patient is going to react subsequently. Patients should have frequent physical examinations and examination of the blood before each roentgen treatment or before each small series of treatments in order to make sure that the blood or the patient himself has not been affected adversely by too much treatment. As soon as the leukocyte count begins to show an abrupt fall in leukemia, it is time to spread the treatments a little further apart. You cannot say at the beginning that you are going to give a patient 400, 600 or 1,000 roentgens. You must judge that as you go along and spread your treatment as the count begins to drop abruptly. When the count reaches 30,000 or 20,000 or thereabouts, you must consider the possibility of discontinuing treatment altogether for a time. If you do not do this, dangerous leukopenia may supervene. Thrombocytopenia may develop, with striking hemorrhagic manifestations, or anemia may increase. The indications then for resuming treatment after it has been stopped are similar to those at the beginning, except that the patient must be observed at frequent intervals, perhaps of not more than six or eight weeks, in order to detect changes which might indicate an impending relapse, which may be forestalled. These indications are a rapid increase in white blood cells, a persistent increase or high level of the basal metabolic rate, the presence in the blood of increasing numbers of very immature cells, and the symptoms associated with enlargement of the organs.

What are the contraindications for the treatment of leukemia? Some say that acute leukemia should not be treated with x-rays. There is no other treatment which is effective except perhaps transfusions, which are only palliative, the effect lasting for a few days. I think that it is justifiable to treat acute leukemia with x-rays, but one must expect little from such treatment. Occasionally if so treated the disease will be converted into subacute or chronic forms. If there are large numbers of blast cells in the blood, as in a terminal stage of chronic leukemia or in acute leukemia, many feel that treatment should not be given. I believe that this is no contraindication for treatment but that one can expect relatively little from it. Some patients will respond favorably. Leukopenia is often regarded as a contraindication for the treatment of leukemia. I do not consider it so unless the leukopenia has been brought about as a result of treatment with arsenic, benzene (benzol), x-rays or radium. Spontaneous leukopenia in leukemia is not a contraindication for treatment, and in some cases the treatment will cause the leukocyte count to rise rather than fall. Thrombocytopenia and severe anemia are also not contraindications for the treatment of leukemia unless they are brought about as a result of treatment. If they are brought about merely as a result of the disease, they frequently will respond satisfactorily to treatment. However, one must gage the treatment cautiously in such instances. Fever also is a frequent accompaniment of leukemia and is not a valid contraindication for treatment, particularly a low grade fever. It will frequently disappear after treatment. Pregnancy, I think, although it rarely occurs in leukemia, is a pretty strong indication against treatment with x-rays or radium because of the untoward effects on the fetus.

The benefits of treatment may also be observed in the effects on the enlarged lymph nodes and in statistics relating to the duration of life. In a case of leukemia with enlarged mediastinal glands, marked reduction in their size may occur within a few days after treatment. The question Does treatment prolong the life of a patient with leukemia or lymphoblastoma? frequently comes up for discussion. Dr. Minot's study tended to show that it does not. Certainly in isolated instances it does, but not in the great majority of cases, although the patient is made comfortable and is enabled to have a much more satisfactory life. The observations of others are essentially the same as those of Minot.

In polycythemia vera it is important to give patients more roentgen treatment than is usually required in leukemia. The point of application of the x-rays is often different, in that patients with polycythemia vera may be treated over the bones more effectively than patients with leukemia; also spray irradiation is perhaps more effective and less dangerous in polycythemia than it is in leukemia. Polycythemic patients are treated only if they have symptoms, the purpose being to lower the production of red blood cells and hemoglobin by the effect of x-rays on the bone marrow cells.

METHODS OF TREATMENT

DR. REZNIKOFF: The second phase, the x-ray aspects, will be taken up by Dr. Carty.

DR. JOHN R. CARTY: X-rays and radium are used simply for palliation. Owing to the fact that it will be necessary to use x-rays over a period of time, particular care should be taken to avoid injury to the skin. Too vigorous treatment should not be attempted.

particularly in single doses. With use of multiple small doses one can watch the patient more carefully, and one is not likely to produce leukopenia.

I agree with Dr. Forkner that the question of leukocyte count alone should not be taken as a guide to roentgen therapy, as there are patients with a leukocyte count of 70,000 or even 100,000 cells who are quite comfortable, and if the cells are reduced below that by x-rays they feel worse. Similarly, a patient with 60,000 or 70,000 cells might be very uncomfortable and made to feel better by treatment.

In general, two methods of treatment are employed. With the first, treatment is applied to a limited area directly over the bone and spleen in myelogenous leukemia, and over the enlarged lymph nodes in lymphatic leukemia. With the second method the entire body is treated by means of very small doses by the spray method as mentioned by Dr. Forkner. While the dose per se is small the body area is large, and the absorption of x-rays may be considerable. I believe that the latter method is particularly useful when the patient is unusually radiosensitive, but I am not as enthusiastic as are some people about that method because I feel it is hard on the marrow. I believe that 200 kilovolt peak therapy with filtration of from 1 to 2 mm. of copper is preferable to medium wave or intermediate therapy with less filtration simply because the skin seems to endure this type of radiation better, and the more the skin can be conserved, the better.

One must exercise great care in treating children with leukemia as I have occasionally seen violent reactions following small doses.

After the first series of treatments the radiation needs of the leukemic patient can generally be determined. It is important to determine this not only as a guide for future doses but also for its prognostic significance.

With lymphoblastoma, Hodgkin's disease and lymphosarcoma, while the outlook is desperate, occasional instances of authentic cure are reported, and I believe that the results obtained by x-rays have improved considerably with the improvement of technic.

A constant check on the condition of the mediastinum is important because enlargement may occur there without any symptoms whatever. Another important point is that the treatment of the mediastinum, when there are pressure symptoms, must be given cautiously with the patient hospitalized during the first two or three treatments; otherwise difficulty may be encountered because if the patient is radiosensitive the lymph nodes will swell before decreasing in size.

Patients who are moribund or who have extreme leukopenia or anemia are usually best not treated. If, however, this occurs early in the disease I believe that very cautious treatments may be given, for a rise of the leukocytes may occasionally occur, as Dr. Forkner has stated.

In polycythemia vera we again use x-rays as a palliative, not a curative, agent. Local or general body exposure (spray) may be given. The long and flat bones, including the sternum, are treated. Careful check on the blood should be maintained. It is well to discontinue treatment if the white cell count goes below 5,000.

EFFECT OF IRRADIATION

DR. REZNIKOFF: The pathology will be presented by Dr. Furth.

DR. JACOB FURTH: The therapeutic application of x-rays in leukemia and allied diseases followed empir-

ical observations of Pusey (1902) and Senn (1903) on patients and the experimental studies of Heinecke (1904) on animals that indicated the high susceptibility of blood cells to x-rays. Nuclear degeneration in lymphocytes is evident within a few hours after irradiation, increasing in severity during successive days. A transient initial rise in white blood cells is followed by leukopenia reaching its depth several days after irradiation, the severity of the leukopenia depending on the dose. The effect of a given dose is the same regardless of intensity, the product of intensity and time being constant, as expressed by the Bunsen-Roscoe law. This does not hold when feeble intensities are used. Different types of radiation act the same way, the quantity of radiating energy absorbed being the main factor that determines the effect of the radiation. Among blood cells the lymphocytes are the most susceptible to x-rays but myelogenic and erythrocytic cells are likewise readily destroyed, so that severe general irradiation is followed by aplasia of bone marrow and atrophy of lymph nodes and spleen. Monocytes seem to be the most resistant type of leukocytes.

The degree of sensitivity to x-rays is characteristic for each cell type. In general, the radiosensitivity of cells seems to be directly related to their reproductive capacity and inversely related to the degree of differentiation, as stated by Bergonie and Tribondeau (1906). X-ray susceptibility of the same cell type varies with stages of cell development, the peak of susceptibility being during mitosis. The difference may be as much as eightfold (Mottram). Leukemic cells are as a rule more susceptible to x-rays than normal cells but the difference is quantitative and overlapping. For instance, 10 per cent of cells of one type may be killed by a dose of x-rays which may be only one tenth of that needed to kill the more resistant 10 per cent of the same population (Scott). This is in complete agreement with our experimental studies on leukemic blood cells. When general irradiation is given, there seems to be no dose that will kill all malignant cells without producing injury fatal to the host. The radiosensitivity of different malignant cells of the same type varies and cannot be predicted with certainty. I shall modify slightly Dr. Forkner's remarks by saying that there is a variation in susceptibility of different malignant strains of the same cell type (e. g. leukemic lymphocytes), but animal experiments indicate that the sensitivity of the same strain of malignant cells is constant in different hosts.

X-ray death is not immediate. Though fatally wounded, the cells may migrate and exhibit other evidence of life for hours or days following irradiation, a phenomenon referred to as delayed lethal effect. The incubation period of this delayed lethal effect depends on the dose. Ignoring this factor in roentgen therapy might result in overdosage.

X-rays lower resistance of the host to infections. Irradiated animals may succumb to infection by otherwise harmless micro-organisms of which they are carriers. Prophylaxis of latent infections should therefore precede therapeutic irradiation.

X-rays injure cells by direct effect; hence the beam of radiation is best directed to masses of neoplastic cells. The usual sarcoma and carcinoma as a rule are not definitely influenced by indirect irradiation, but there may be an indirect effect in leukemia, though this, if present, is slight and variable. This indirect effect has not been well analyzed, and almost every affirmative observation can be matched with a contradictory report.

Nevertheless the numerous theories proposed to explain the assumed indirect effect, such as those postulating necrohormones, toxins or enzymes liberated from the tissues, or circulating electrons, are widely quoted. A general effect may follow irradiation, but I do not know of any experimental work indicating the production of a specific x-ray change by indirect irradiation, for example, atrophy of bone marrow or of spleen. The whole question of indirect irradiation effect requires reconsideration. The indirect local effect is better known. Injury to the soil of the neoplastic cells, for instance obliteration of vessels, doubtless retards neoplastic growth.

It is frequently stated that small doses of x-rays have a stimulating effect. This, if present, is slight and transient. Prolonged leukocytosis, lymphocytosis or erythremia has never been produced by x-rays. The x-rays are useful to destroy an excess of white cells in leukemia and erythrogenic foci in polycythemia but useless to stimulate hypofunctioning blood-forming organs. Neoplasia by irradiation occurring after a latent period of from ten to thirty years is a different process. The opinion that leukemic cells are stimulated to maturation by x-rays is not supported by experimental studies.

The subject of radiobiology is as fascinating as it is important in medicine. Its many aspects are admirably reviewed in the "Handbuch der gesamten Strahlenheilkunde," edited by Lazarus. A similar encyclopedia of basic knowledge is the three volume set of Duggar on the biologic effect of radiation. The two small volumes of Colwell and Russ "Radium, X-Rays and the Living Cell" and "X-Ray and Radium Injuries" are good reading and reference books. A good review of the pertinent medical literature can be found in Forkner's book "Leukemia and Allied Disorders" and in Selling and Osgood's section in Downey's "Handbook of Hematology." Among the recent individual contributions on the biologic effect of x-rays and radium, Scott's monograph in the British Medical Research Council Series (1937) is outstanding.

DISCUSSION OF QUESTIONS

STUDENT: Is it always necessary to hospitalize a patient when giving roentgen therapy for leukemia?

DR. FORKNER: No, but I think it is advisable for the initial series of treatments because one is dealing with a number of unknown factors. Once a series of treatments has been given, one knows the patient much better.

STUDENT: How often does one check the blood of such an ambulatory patient?

DR. FORKNER: About every six weeks or twelve weeks if the patient is doing well. More frequent visits are necessary if he is not doing well. A great deal depends on how ill the patient is and in what stage the disease is.

DR. REZNIKOFF: Our custom here is to check the blood within a week after the cessation of the series of treatments. Then if the patient is normal we have him come back within at least a month.

STUDENT: According to the literature there are so-called cures with roentgen therapy, pretty definite cures. Dose that occur only in early cases?

DR. CARTY: There have been a few reported cures by x-rays where there has been definite histologic evidence of lymphoblastoma. Those are early cases.

DR. FORKNER: I know of only two cases of leukemia in the literature in which a cure has followed treatment with x-rays, and those were both early cases of chloroma. I think that none of the other cases that have been reported, of which there are a fair number, will stand critical judgment. It should be pointed out that the diagnosis of leukemia is sometimes extraordinarily difficult and that it may easily be confused with a number of other disorders.

DR. McKEEN CATTELL: Then one cannot say with absolute certainty that the recoveries have been due to the x-rays?

DR. FORKNER: One of those mentioned was associated with excision of a chloromatous tumor in which the blood had only a few myelocytes. The other patient had some myeloblasts in the blood and there were a number of tumors scattered about. A biopsy was taken for confirmation of diagnosis. The patients, both children, were alive and well two and one-half years later, which I think is adequate time for one to say that cure had resulted. I have never seen an untreated chloroma last that long.

STUDENT: I should like to ask Dr. Carty if anything is known definitely about the mechanism of the x-ray reactions which are observed after therapy. I refer to nausea and vomiting and sometimes vague abdominal pains.

DR. CARTY: There are many theories. We really do not know much about it. The theories are, first, that the effect is psychic; second, that there is a change in the composition of the blood; third, that there is some noxious gas like nitrous oxide generated by the machine; and fourth, that there is some breakdown product which poisons the patient.

I have seen patients who have had radiation become nauseated entirely on the basis of psychic reaction. One patient was taken to the treatment room early in the morning, and the machine had not been running. I put that patient under the machine and had it make a noise without giving off any x-rays, and the patient promptly vomited after the lapse of the usual time. Undoubtedly some reactions are based on complex physiologic-chemical effects, and not much is known about them. Many remedies are employed for these reactions, and that fact alone is an indication that no one therapeutic measure is worth much.

STUDENT: Has there been any experience in this hospital with the use of vitamin B complex in the treatment of nausea and vomiting following irradiation?

DR. CARTY: We have tried it, but not with startling results. Liver extract did seem to do some good in certain cases. A high vitamin intake, including orange juice and grapefruit juice, is sometimes helpful, and also to treat the patient on an empty stomach, but I know of no therapeutic measure that is universally effective.

DR. FORKNER: These patients have fewer untoward effects following treatment if they are on a low protein and a high carbohydrate diet because there is much protein destruction and elimination of its metabolites as a result of the x-rays. Therefore, if possible, for a few days prior to treatment and for a week or so afterward a low protein, high carbohydrate diet may be given, sometimes with benefit.

DR. REZNIKOFF: Dr. Forkner, will you tell us something about roentgen therapy in thrombocytopenic purpura and granulocytopenia?

DR. FORKNER: There have been several series of studies on thrombocytopenic purpura and granulocytopenia, so called, in which it has been thought that small stimulating doses of x-rays applied to the bones have been effective in inducing remissions, but other series of cases have not verified this. It seems to me unlikely that irradiation would be effective in that condition or in agranulocytic angina. Concerning patients who have thrombocytopenic purpura haemorrhagica it has been said that irradiation of the spleen will accomplish in a measure what splenectomy might accomplish and can be applied to patients whose spleens it is for one reason or another impossible to take out. I think this method is definitely secondary to splenectomy and should not be used if splenectomy can be done fairly safely. When it cannot, I think it is justifiable to try to induce a remission by intensive treatment.

DR. REZNIKOFF: I would go even further and say that in the case of granulocytopenia it is a dangerous procedure. It is my impression that, while these cases show a temporary effect as demonstrated by a response of the white blood cells, they subsequently show a marked depression, below levels seen before the treatment was started.

DR. HARRY GOLD: Would we be safe in assuming that the therapeutic effects of x-rays in these various blood diseases that have been mentioned result from the destruction of cells and that there is no other effect of x-rays on any underlying process responsible for the disease?

DR. FURTH: The direct destructive effect of x-rays is something definite. It can be demonstrated by both in vivo and in vitro experiments. In experimental leukemia, destruction of leukemic cells explains the prolongation of life. The indirect effect is not well understood but it seems to be present. There is some regression of the size of the lymph nodes, and the leukocyte count is reduced beyond what one would expect from irradiating the blood leukocytes circulating within the therapeutic field during the time of irradiation. The number of blood cells destroyed by direct irradiation is enormous but the indirect effect is very uncertain; I believe that it is slight and its mechanism not understood.

DR. REZNIKOFF: In the cases of polycythemia, spray irradiation, which would be indirect irradiation to some extent, has given us the most prolonged remissions. We have patients who have had spray radiations of from 25 to 50 roentgens with a maximum of six treatments who have gone for as long as a year, and most more than forty weeks, without change in the blood count, whereas previously with acetylphenylhydrazine or spot radiation over the bone marrow and spleen we have rarely been able to keep them more than a few months at the most. Dr. Carty, you were not enthusiastic about spray radiation. Did you mean to include polycythemia?

DR. CARTY: No, I referred particularly to leukemia.

DR. REZNIKOFF: Have you anything to say about grenz radiation, the so-called Buckie radiation which penetrates only 3 mm.?

DR. CARTY: I have had no experience with it myself, but Buckie claims that a reduction in red cells is produced. If so, that would tend, it seems to me, to be in favor of some indirect mechanism.

In this connection I should like to ask Dr. Furth if he is familiar with some work that is being done on

irradiated blood in hopeless cancer cases in which the blood is removed from the patient, irradiated and then returned to the body.

DR. FURTH: I am not certain that a specific effect has been demonstrated by means of injections of irradiated blood. Dr. Forkner might be more familiar with the literature. I am impressed by the lack of controls in these experiments.

DR. FORKNER: I think the results in most of the cases that have been recorded are equivocal. Most of the cases studied have been complicated by other factors which might well account for the remission. The original work, I think, was done by Capps and Smith in 1907 and then was repeated by Szilard and more recently by a number of other workers. There is still disagreement, but I think the general feeling is that it does not work, and any effect described has been very transitory.

One has to be cautious about treating the bone marrow or the bones of patients with leukemia. That does not apply in polycythemia, but in leukemia when treating the bones one is much more likely to induce a more severe anemia. Instead of the red blood cells promptly coming up as the white blood cells come down, the red blood cells are apt to drop further, and the effect is less beneficial; also the thrombocytes are sensitive to radiation, particularly direct radiation. I think one is more apt to produce thrombocytopenia in treating the bones than in treating the spleen or the chest.

DR. CATTELL: Under what circumstances is radium the treatment of choice for blood conditions?

DR. CARTY: I think it is simply a matter of convenience. Of course, the radiation is quite different in wavelength; the gamma radiation of radium is different from radiation of 200 kilovolt peak. Practically speaking, the effects can be considered the same.

DR. FURTH: In the treatment of localized masses of neoplastic blood cells, as in the treatment of cancer, radium is excellent and might in some instances be preferred, but in treating a diffuse systemic disease like leukemia x-rays seem preferable.

DR. FORKNER: Yet one can apply radium to the spleen in leukemia and get a satisfactory effect, a general effect, on the bone marrow.

STUDENT: Considering the fact that there may be an indirect factor, such as mentioned by Dr. Furth, is there any reason why the blood of a polycythemic patient who has been given roentgen treatment should not be used for transfusion?

DR. REZNIKOFF: I see no reason why the blood from a polycythemic patient should not be used for transfusions. We have used it and have never regretted its use, but I don't quite understand why the polycythemic patient need be irradiated first.

STUDENT: I meant, was there anything wrong in using the blood of such a person?

DR. REZNIKOFF: I think the effect of the x-rays would disappear in a relatively short time. The amount of x-rays the recipient would have would be negligible.

DR. CARTY: We have used the term "stimulating dose." I think it is misleading. X-rays probably do not produce an effect comparable to the stimulation of a gland, speaking from the physiologic standpoint. The so-called stimulating effect is probably in the nature of a minimal injury.

DR. FORKNER: I think that the term came from the original work of Murphy, Nakahara and Strum, in which they found that small doses of x-rays applied to animals induced an increased production of lymphocytes in the germinal centers of lymph nodes and an increase in the number of lymphocytes in the blood, but I think their results were also interpreted as being secondary to a minimal destruction or a minimal damage to the cells.

STUDENT: I want to ask about the use of radioactivated elements in the treatment of leukemia, with the radioactivity lasting three or four days. Has that been used at all?

DR. FORKNER: Lawrence and his associates in California have treated patients with various disorders, particularly leukemia, with irradiated phosphorus. They have found that by irradiating phosphorus and then giving patients this to drink they can induce a satisfactory remission, which is fairly prolonged in its effect. When the effects wear off all the patient has to do is to take another drink and he again gets a satisfactory effect. The treatment has not been carried over a long enough time to know just how permanently useful it is going to be. I think the results are promising. It may turn out to be the most effective form of treatment of leukemia by irradiation.

DR. REZNIKOFF: Dr. Harrison Martland has given rats radioactive liquids and has shown how dangerous, or rather how effective, the radioactive material can be in causing depression of the bone marrow. One of the difficulties, as he points out, is that when a remedy is applied locally the dosage can be controlled and stopped, whereas if an excess is taken and is stored there is no means of getting rid of it.

DR. FORKNER: I think that applies to radium and to the thorium group of preparations, but this irradiated phosphorus has a half life of only fourteen days.

DR. CARTY: That brings up the opaque material colloidal thorium dioxide. I have discussed the use of that substance with Dr. Martland; he is strongly against it and feels that later on there may be some bad end results from its use.

DR. GOLD: There is a great deal of exploitation of radioactive waters and radioactive baths.

DR. FORKNER: There is danger in their use. A preparation called Radiothor a few years ago was sold widely for the treatment of arthritis and various other disorders. I had that substance appraised at the Rockefeller Institute, and it was found to be definitely radioactive and we considered the recommended doses dangerous.

SUMMARY

DR. REZNIKOFF: Dr. Gold, will you summarize?

DR. GOLD: In today's conference we have considered x-ray radiation in the therapy of blood diseases, its indications, the method of application, some of the mechanisms involved in its action, the dosage and the dangers.

The effects of radium and x-rays are similar and the choice of one over the other seems, from the discussion, to be chiefly a matter of convenience.

Some of the fundamental facts concerning the response of blood cells to radiation help one to understand better the problems and difficulties involved in its use. Blood cells are very susceptible to radiation, some more than others. The most sensitive cells are the lymphocytes, and the most resistant the monocytes. Leukemic

cells are more susceptible than normal ones. There are marked differences in sensitiveness among cells of the same type depending on various factors, as the stage of their development, and this applies to both normal and leukemic cells. There is so much overlapping in the sensitiveness that it is impossible to find the dose of radiation which will destroy all the abnormal cells without causing serious destruction of normal ones as well.

The long latent period after the application of radiation before effects appear is a source of danger and must be taken into account to avoid overdosage.

The effect of radiation appears to be chiefly that of cellular injury, and the so-called stimulating effect of small doses may be merely a matter of minimal injury. So-called stimulating effects of small doses are slight and transient and of doubtful value in hypofunctional states of blood-forming organs such as thrombocytopenic purpura and granulocytopenia.

Although there is some indication that radiation may produce some indirect effects, the main effects appear to be exerted by direct destructive action on the abnormal cells, suggesting the desirability of applying radiation directly to the pathologic tissues.

Various technics for the application of radiation therapy were discussed. The effective dose is the amount of energy absorbed by the tissues, and it depends on the product of the intensity of the irradiation and its duration. Since patients differ in their sensitiveness, dosage, as in the case of a drug, needs to be established for each case individually.

Some of the dangers of irradiation were discussed, particularly the effect of overdosage in depressing unduly the various elements of the bone marrow. Minor reactions such as nausea and vomiting, and methods for their control, which were also considered, appear sometimes to be due to psychic factors.

In leukemia, the indications for treatment are such symptoms as fatigue, fever, loss of weight, pain due to pressure, and itching. The treatment reduces the size of enlarged glands. Occasionally it prolongs life and, in many, symptoms are relieved. At times roentgen treatment may delay the appearance of symptoms or prevent relapse. In leukemia the radiation is more safely applied to the spleen or the chest than to the bones, because of the danger of reducing the number of thrombocytes and promoting severe anemia. The view has been expressed that there are no contraindications for roentgen treatment of leukemia when it is necessary by reason of the presence of symptoms, with the exception of leukopenia, thrombocytopenia, or anemia when these have been brought about by previous roentgen treatment. Pregnancy is a contraindication because of the effect of radiation on the fetus.

In polycythemia vera, more treatment is usually necessary than in leukemia. The object of the therapy is to depress the bone marrow cells enough to reduce the number of circulating red blood cells. The view has been expressed that this condition responds better to spray radiation than to spot radiation over the bones and the spleen.

In purpura haemorrhagica, intensive treatment of the spleen is sometimes effective but should be used only when for some reason splenectomy is inadvisable.

It has been emphasized that in leukemia and in polycythemia vera the prime indication for radiation therapy is not merely the existence of the disease but the presence of symptoms. Radiation therapy is, in these conditions only palliative. It rarely, if ever, occurs.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

GENERAL ELECTRIC GALVANIC GENERATOR ACCEPTABLE

Manufacturer: General Electric X-Ray Corporation, 2012 Jackson Boulevard, Chicago.

The General Electric Galvanic Generator is used in muscle and nerve stimulation, common ion transfer therapy and electrolysis. It is a portable unit 15 inches wide, 11 inches deep and 6¼ inches high, and the shipping weight is 50 pounds. Accessories include two rubber covered electrode cords with

General Electric Galvanic Generator.

friction grip terminals and one spongiopilene dispersive pad with a metal back 6 by 8 inches in size. Models are equipped for operation on 105/125 volt, 50/60 cycles alternating current, 210/250 volt, 50/60 cycles alternating current and 105/125 volt direct current.

The apparatus contains a full wave vacuum tube rectifier and a filter system which converts alternating current into a smooth "ripple free" direct current. The current to the patient is controlled by a potentiometer type intensity regulator so that the current will be uniformly varied from zero to maximum. The transformer is air cooled, and safety against electrical shock is assured by insulation of the secondary from the primary winding. A two scale milliammeter (0-20-200) with a selector switch on the meter permits choice of either scale. A line switch and polarity switch are also supplied.

When direct current is used, a rectifying and filtering system is not provided. However, a series of relays insure that the grounded side of the direct current system is connected to the patient.

The firm submitted as physical evidence an oscillogram demonstrating that the rectified direct current is ripple free.

The unit was submitted to a qualified investigator for clinical use and he reports that it was satisfactory for use in common ion transfer and muscle stimulation.

The Council voted to accept the General Electric Galvanic Generator for inclusion on the Council's list of accepted devices.

BURDICK SWD-52 SHORT WAVE DIATHERMY ACCEPTABLE

Manufacturer: Burdick Corporation, Milton, Wis.

The Burdick SWD-52 is a portable short wave diathermy unit designed for medical and minor surgical diathermy. The unit is similar to the previously accepted SWD-50 (THE JOURNAL, Aug. 20, 1938, p. 712) except that a cable with its output circuit and power control rheostat have been provided. The SWD-50 has been accepted for pad technic. Standard accessories include three condenser pads and two cuff electrodes of different sizes and one twelve foot cable. Surgical accessories and a lower cabinet to support the unit are optional.

A two-tube push-pull self-rectified circuit is utilized with loose inductive coupling to the patient's electrodes. The wavelength is approximately 15 meters. The patient's circuit is turned by a wide range, variable resonance control. Three patient's outlets are provided, one for use with large pads and average spacing, one for small pads with thicker spacing and one for the cable. Radio interference is minimized by steel construction, insulation and an inductance capacity filter in the line supply.

The firm claims that the unit provides a 300 watt output as measured by a lamp load, photoelectric cell and wattmeter, using an input of 800 watts. The final transformer temperature after a two hour run at full load was within the limits of safety.

Burdick SWD-52 Short Wave Diathermy.

Since the cuff circuit is the same as that used in the SWD-50 unit, the firm did not resubmit deep heating tests for this technic. No evidence was submitted for the pad technic. In order to demonstrate the production of heat deep within human tissue by the unit with the coil technic, the firm submitted six tests. Four turns of the cable were made around the thigh and a five-eighths inch felt spacing was used. Power was applied only up to the patient's skin heat tolerance. Following are the average temperatures received in degrees F.:

	Deep Muscle	Oral
Initial	97.8	98.2
Final	106.6	98.5

The apparatus was used clinically by the Council and was found to be satisfactory. It was efficient in tissue heating with cable and cuff technics. The external construction of the machine is stable.

The Council voted to accept the Burdick SWD-52 Short Wave Diathermy Unit for inclusion on the Council's list of accepted devices.

Council on Foods

AT THE REQUEST OF THE COUNCIL ON FOODS, THE BOARD OF TRUSTEES GRANTED THE COUNCIL AN APPROPRIATION FOR THE PURPOSE OF MAKING A STUDY OF THE PROBLEM OF LEAD IN FOODS. THE EXPERIMENTAL WORK WAS DONE IN THE LABORATORY OF THE DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY, NORTHWESTERN UNIVERSITY SCHOOL OF MEDICINE, THROUGH THE COURTESY OF DR. A. C. IVY. THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT, REPRESENTING A PART OF THE WORK THAT HAS BEEN DONE UNDER THIS SPECIAL GRANT.

FRANKLIN C. BING, Secretary.

EFFECT OF CALCIUM AND PHOSPHORUS ON RETENTION OF LEAD BY GROWING ORGANISM

LUDWIG G. LEDERER, M.D., PH.D.

AND

FRANKLIN C. BING, PH.D.

CHICAGO

Recent studies employing sensitive analytic methods have shown that traces of lead are present in practically all common foods which have been examined. Even minute amounts of lead may be detrimental to health if they accumulate in the body. To draw conclusions about the significance of the traces of lead that are ingested under ordinary conditions would require careful study and more data than now are available. The problem of lead in foods has been the subject of extensive reviews by Calvery¹ and Monier-Williams.² On the basis of evidence now available, lead must be considered a potential hazard and all possible contamination of food products with lead should be guarded against. The Council on Foods³ has repeatedly emphasized this point of view.

This report, which is part of an experimental study made possible by a special grant of the Board of Trustees of the American Medical Association to the Council on Foods, presents the results obtained in an investigation of the influence of calcium and phosphorus in the diet on the storage of lead in the growing organ-

1. Calvery, H. O.: Chronic Effects of Ingested Lead and Arsenic: A Review and Correlation, J. A. M. A. 111: 1722-1728 (Nov. 5) 1938.
2. Monier-Williams, G. W.: Lead in Foods, Reports on Public Health and Medical Subjects, No. 88, London, Ministry of Health, 1938.
3. Lead in Foods, in Report of Annual Meeting of the Council on Foods, J. A. M. A. 112: 680-681 (Aug. 19) 1939.

ism. It is becoming recognized that the composition of the diet has an important effect on the retention of lead. The data reported herein support the view that increased amounts of calcium in the diet diminish the amount of lead which is stored in the body. The data also show that the amount of phosphate in the diet has no effect on the storage of lead.

EXPERIMENTS

Procedure.—Albino rats which had been reared in the laboratory were selected as experimental animals. At the age of 3 weeks the rats were weaned and fed for one week on Sherman's diet B,⁴ which consists of ground wheat and dried milk with 1.3 per cent of sodium chloride. The animals then were divided into groups, placed in cages, each containing three or four animals, and fed the experimental diets. Each group contained approximately equal numbers of males and females and representatives from different litters. The animals were selected also so that the average weights of the rats in each group were approximately equal.

The experiments were planned to study the effect of both the level and ratio of dietary calcium and phosphorus on the retention of lead. The diets used were patterned after those devised by Shohl.⁵ The basal diet consisted of 79 per cent of yellow corn meal, 20 per cent of wheat gluten flour and 1 per cent of sodium chloride. The calcium, phosphorus and lead contents of the basal diet were determined. To each kilogram of the mixture was added 100 mg. of basic lead acetate, except for the diets fed groups J and K. Appropriate amounts of calcium carbonate or potassium phosphate, or both, were added to the basal diet so as to produce diets having the composition in terms of calcium and phosphorus shown in table 1. The rats were supplied distilled water from pyrex containers. Ordinary wire cages with false bottoms were used because it was not considered essential to devise a lead-free cage for the purpose of these experiments.

TABLE 1.—Composition of the Diets

Group	Calcium Percentage	Phosphorus Percentage	Ratio Ca:P	Added Lead Mg. Pb per Kg.
A	2.0	0.5	4.0	100
B	1.0	0.5	2.0	100
C	0.5	0.5	1.0	100
D	0.25	0.5	0.5	100
E	0.12	0.5	0.25	100
F	0.25	0.12	2.0	100
G	2.0	1.00	2.0	100
H	0.5	0.25	2.0	100
J	2.0	1.00	2.0	0
K	0.25	0.12	2.0	0

The basal diet consisted of yellow corn meal 79 per cent, wheat gluten flour 20 per cent and sodium chloride 1 per cent. It contained approximately 0.02 per cent of calcium, 0.10 per cent of phosphorus and 1.82 mg. of lead per kilogram by analysis. The calcium and phosphorus contents of the diet were adjusted by addition of calcium carbonate and dihydrogen potassium phosphate. Lead was added as basic lead acetate.

The animals were allowed to consume the diets freely for three weeks, when the experiment was terminated. The rats in groups J and K, which received no added lead in their food, were given daily by intraperitoneal injection 100 micrograms of lead in the form of a solu-

tion of lead acetate during the same period. At the end of the experiment roentgenograms were taken of each animal. The animals then were killed under ether anesthesia and, with precautions to avoid lead contamination, the liver, kidneys and femurs were dissected from each animal. The femurs of each animal were dried, ashed in an electric muffle furnace at a temperature which did not exceed 500 C. and analyzed for lead. In order to obtain sufficient material for analysis, it

TABLE 2.—Lead Content of the Femurs

Group	No of Rats	Dietary		Average Composition of Both Femurs			Micrograms of Lead per Gm. Dried Bone \pm S. D.
		Calcium, %	Phos-phorus, %	Dry Weight, Gm.	Ashed Weight, Gm.	Ash in Dried Bones, %	
A	9	2.0	0.5	0.223	0.103	46.2	77 \pm 32
G	10	2.0	1.0	0.206	0.095	46.1	61 \pm 21
D	9	0.25	0.5	0.186	0.075	40.3	223 \pm 45
F	10	0.25	0.12	0.196	0.082	41.8	213 \pm 46

was necessary to pool the livers or kidneys of from two to four animals. These tissues were dried, ashed and likewise analyzed for lead.

Lead was determined by means of the dithizone method described by Clifford and Wichman⁶ with some of the modifications suggested by Laug.⁷ A titration-extraction procedure was used.⁸ The method, which need not be described, was studied until confidence could be had in the results. Duplicate determinations checked closely. Small amounts of lead added to evaporated milk could be recovered with a maximum variation of about plus or minus 10 per cent.

OBSERVATIONS

The animals in the various groups consumed their food in approximately equal amounts. Growth was poor, although none of the animals lost weight. The roentgenograms showed no evidence of a lead line. The bones appeared to be normal in all groups, except that the animals fed diets which were low in calcium had definitely poor bones. This was especially noticeable in groups D, E and F, which were given either 0.12 or 0.25 per cent calcium. No evidence of rickets, which might have been expected in the animals in groups D, E and F, was found in any of the animals. It is quite possible that the inclusion of lead in the diet affects the metabolism of calcium and phosphorus, even if present in the small amounts used in these experiments.

Data on the lead content of the femurs are included in chart 1 and table 2. In the chart are shown the values obtained in the first experiments, where four animals were contained in each group. The data show a marked diminution in the lead content of the femurs as the calcium content of the diet is increased. The animals in group E, for example, which were fed a diet containing 0.12 per cent calcium, had an average of 307 micrograms of lead per gram of dried femur, whereas the animals in group A, fed the diet containing 2.0 per cent calcium, had an average of 43 micrograms of lead per gram of dried femur. The data provided in the

chart also show that the level of phosphorus in the diet has no effect on the lead content of the femurs. The dried bones of groups A and G, for example, both contained 43 micrograms of lead per gram. Both groups received 2.0 per cent calcium in the diet, but the diet fed group G had 1.0 per cent of phosphorus, while the diet fed group A had 0.5 per cent. An even more striking example of the lack of any effect of phosphorus is made evident from a comparison of the results obtained with groups D and F, both of which received diets containing 0.25 per cent of calcium, but in the diet fed to group D there was 0.5 per cent of phosphorus and, in the diet fed to group F, 0.12 per cent of phosphorus. The average amount of lead, expressed as micrograms per gram of dried femur, was 210 in group D and 219 in group F.

In table 2 there is provided a summary of the analyses of the bones of four groups of animals from the data recorded in chart 1 and also from data obtained with additional animals. The later experiments duplicated the earlier series. The amount of lead in the femurs, however, was on the average about 40 micrograms per gram higher in all the groups in the second series. This may have been due to differences in the lead content of the animals at the beginning of the experiment or perhaps to seasonal variations in metabolism. All the data were averaged and the results treated statistically. The table provides the calculated standard deviations of the mean lead content of the femurs in each of four groups of animals. The data show conclusively that the deposition of lead in the bones of growing animals is retarded by increasing the calcium content of the diet. The data also show conclusively

Chart 1.—Decrease in lead content of bone with increasing amounts of calcium in the diet. The solid dots represent values for individual animals receiving 0.5 per cent phosphorus in the diet and different amounts of calcium. The hollow triangles represent values obtained in individual animals receiving diets in which the calcium-phosphorus ratio was made equal to 2.0. The curved line passes through the average values of all the animals. The lack of effect of dietary phosphorus is apparent.

that the phosphorus content of the diet has no significant effect on the amount of lead deposited in the bones. The table provides the average values for the dried weight, ashed weight and percentage of ashed weight in the dried femurs. These data show that the diets

which produced heavier bones containing a greater amount of ash produced bones which contained the least amount of lead. The data also verify in general the observations of Shohl⁵ on the effect of different ratios and levels of calcium and phosphorus on the composition of the bones, although a direct comparison cannot be made because we did not extract the dried bones with alcohol and ether before ashing.

The data on the lead content of the livers and kidneys are summarized in chart 2. Because of the necessity of pooling the samples, the data are not as extensive as in the case of the bones. The lead content of the kidneys reflects the lead content of the bones, being highest in animals having the highest amounts of lead in the bones and lowest in the animals which had the lowest amounts of lead in the bones.

The amount of lead deposited in the kidneys, expressed as micrograms of the element per gram of dried tissue, in general was less than the amount of lead deposited in the bones. The amount of lead deposited in the liver was much smaller. Further, the amount did not vary regularly with the calcium content of the diet.

Chart 2.—Relationship between the lead content of the kidneys and liver and the calcium content of the diet. Each hollow dot represents one analysis, on two or more animals, of the lead content of the kidneys. Each solid dot represents one analysis of the lead content of the liver, representing tissue from three or four animals. The lead content of the kidneys decreases with increasing amounts of calcium in the diet; the content of lead in the liver remains relatively constant.

TABLE 3.—Effect of Injected Lead on Lead Content of Tissues of Rats Fed Varying Amounts of Calcium and Phosphorus

Group	No. of Rats	Diet		Average Lead Content of Tissues in Micrograms per Gm. Dried Tissue		
		Calcium %	Phosphorus %	Femurs	Kidneys	Liver
K	9	0.25	0.12	499 ± 66	147	45
J	10	2.00	1.00	400 ± 64	121	83

The data obtained in the injection experiments are summarized in table 3. The animals in group K received a diet containing 0.25 per cent of calcium and 0.12 per cent of phosphorus. In group J the animals received a diet containing 2.0 per cent of calcium and 1.0 per cent of phosphorus. As shown in the table, the average amount of lead deposited in the bones was about 25 per cent higher in the animals receiving the lower amount of calcium; but the data were variable and the difference between the two means, 499 plus or minus 66 and 400 plus or minus 64, both expressed as micrograms of lead per gram of dried bone, plus or minus the standard deviation of the mean, is not considered significant. Likewise the data in table 3 show that the

amount of lead in the kidneys of the two groups of animals was of the same order of magnitude. The animals receiving the diet containing the lower concentration of calcium had less lead in the liver than the animals receiving the higher amount of calcium, but there were not sufficient data to establish any significance to the difference. It was concluded that when a solution of a lead salt is injected intraperitoneally there is no essential difference in the lead content of the femurs, kidneys or liver. It is clear that the inhibitory effect of calcium on the retention of lead by the growing organism is primarily concerned with reactions that take place in the alimentary tract.

Calvery, Laug and Morris⁹ showed with dogs that a suitable concentration of calcium in the diet tends to prevent a high storage of lead in the bones and soft tissues of the body. It also retarded the onset of violent symptoms of lead poisoning. The calcium contents of the diets which they fed to dogs were 0.28, 0.13 and 0.10 per cent. Grant, Calvery, Laug and Morris¹⁰ also reported an extensive study with rats on the influence of dietary calcium and phosphorus on the storage and toxicity of lead. They fed two basal diets, one containing 0.13 per cent of calcium and 0.44 per cent of phosphorus, and the other containing 0.53 per cent of calcium and 0.22 per cent of phosphorus. Different amounts of lead arsenate were added to the basal diets. It was found that the animals which received a low calcium diet and 512 mg. of lead per kilogram of feed did not thrive, as shown by the condition of the animals and poor growth. The animals were maintained on each diet for an average period of ninety-three days; the animals surviving were killed and the femurs, brains, livers and kidneys were analyzed for lead and arsenic. Large differences in the lead content of the bones and soft tissues were observed in the different groups of animals, the larger amounts of lead being found in the tissues of the animals receiving the lower amount of calcium. Thus with the low calcium diet there was on an average 189 micrograms of lead per gram of dried femur, and with the relatively high calcium diet there was on an average only about 28 micrograms of lead per gram of dried femur.

The results reported by Calvery and his collaborators conflicted with some of the prevailing views on the relationship of calcium and phosphorus to the metabolism of lead. In their classic investigation of lead poisoning, Aub and his collaborators¹¹ not only established the principles for the treatment of this condition but also demonstrated a relationship between the metabolism of lead and that of calcium. Their conclusions may be stated in their own frequently quoted words: "It has been shown by chemical studies with animals that an analogy exists in the metabolism of calcium and lead. Various decalcifying agents have been shown to increase lead output. Conversely, the conditions favoring calcium retention also tend to a complete storage of lead in the bones." In another publication they wrote "Inasmuch as lead metabolism runs parallel

to that of calcium, the lead problem becomes essentially a problem of calcium metabolism."

While there are many data to support Aub's original contention that the elimination of lead which is already present in the bones is dependent on decalcifying processes, there are few data to support the conclusion that conditions which favor the retention of calcium tend also to favor the storage of lead in the bones. Indeed, the data reported here conflict with the latter view.¹² Further, Aub, Robb and Rossmel¹³ fed cats a meat diet or a meat diet plus milk and gave lead carbonate by insufflation, subsequently analyzed the long bones for lead and found no significant differences in the two groups. It is interesting to note that in our experiments in which lead was given by the parenteral route no difference could be found in the lead content of the tissues of animals receiving diets markedly different in calcium content.

In drawing conclusions about the effect of diet on the metabolism of lead, it is important to make clear whether one is dealing with lead already stored in the bones or with lead that is in the diet which is fed. Much confusion has resulted from failure to state the conditions under which the conclusions have been drawn. For this reason it is necessary to describe in some detail the data available in the literature, as they pertain to the results of the present study.

In 1932 Shelling¹⁴ reported some experiments with rats which indicated that the phosphate content of the diet was of more importance than the calcium content. He fed young rats an adequate diet to which was added 1.5 per cent of basic lead carbonate plus calcium carbonate, disodium phosphate or basic magnesium carbonate. Vitamin D in the form of viosterol in oil was given to some of the animals. As judged by growth, appearance and longevity, the rats receiving the added magnesium carbonate fared worst, and those receiving calcium carbonate fared almost as poorly. The animals receiving the stock diet with added lead carbonate thrived a little better; but the rats fed the same diet with the addition of sodium phosphate did best of all. The rats receiving vitamin D died much earlier than their mates which did not receive the vitamin, except for the animals receiving additions of phosphate, all of which thrived irrespective of vitamin D. No analyses of the lead content of the animals were made.

An extension of Shelling's work was made by Sobel and Kramer and their collaborators, and their most recent report summarizes the earlier data.¹⁵ They fed young rats diets which had 0.025 per cent of calcium and 0.262 per cent of phosphorus, 1.02 per cent of calcium and 0.262 per cent of phosphorus, and 0.025 per cent of calcium and 0.857 per cent of phosphorus. The lead content of each diet was from 0.80 to 0.82 per cent. After five days on the experimental diet half of the rats in each of the three groups were given

vitamin D in the form of viosterol in corn oil. At the end of twenty-nine days the animals were killed and the blood and femurs were analyzed for lead. In each instance the animals receiving vitamin D had more lead in the bones than the controls receiving the same diet but no vitamin D. The bone ash in the animals fed vitamin D likewise was higher but still much below normal for rats of the same age. The highest amount of bone ash was found in the group receiving 1.02 per cent of calcium plus vitamin D, and this amounted to only 37.9 per cent of the fat-free dried bone. The high calcium diet resulted in a lower amount of lead in the bones. The high phosphate diet resulted in a still lower amount of lead in the bones.

The lead content of the diets used by these investigators amounted to approximately 8 milliequivalents of lead per hundred grams, about eighty times the concentration of lead in our diets. The calcium content of the diets used by Sobel and others was either 1.25 or 51 milliequivalents per hundred grams, the phosphorus either 25 or 83 milliequivalents per hundred grams. It would thus seem that these authors were observing the effects of lead on the metabolism of calcium and phosphorus in addition to the effects of calcium and phosphorus on the metabolism of lead. With these diets they confirmed Shelling's observations that the addition of phosphate to the basal diet had a beneficial effect. Because five of their six experimental groups had less ash in the femurs than control animals at the age of twenty-three days, the authors concluded that lead may be deposited in the bone while calcium is being withdrawn. They did not discuss the possibility of decalcification of the shaft of the bone and calcification of the epiphysis, which probably is what took place. It is known that lead is deposited in the trabeculae. Further, the groups receiving vitamin D uniformly had more bone ash and more lead than their corresponding controls. If attention is focused on these experimental animals, it equally well could be concluded that their results are in harmony with the view that conditions which favor the deposition of calcium salts in the bone also favor the deposition of lead.

Tompsett¹⁶ recently reported that he fed adult mice two different diets containing different amounts of fat and supplying relatively high or low calcium intakes. To these rations he added supplements of lead. In experiments of two weeks' duration he found much less lead in the bodies of mice receiving the so-called high calcium diet. He suggested as an explanation of the protective effect of high calcium diets that the reaction of the intestinal contents is made more alkaline and in this manner decreases the solubility of lead, which is assumed to be present as lead phosphate. This explanation of the beneficial effect of calcium in the diet is unsupported by direct experimental evidence. In addition, Tompsett fed mice added fat and also vitamin D in the form of cod liver oil and reported no effect on lead storage from either. The failure to note any effect of vitamin D on lead stored in the body may be ascribed to the fact that he used adult animals, whereas Sobel and his collaborators used young, growing animals.

There is evidence that lead phosphate is not the salt which would be precipitated from a solution containing lead, phosphate, calcium, chloride and various other sub-

stances which may be found in the intestinal contents and in the blood serum. Jowett¹⁷ found that the precipitate which is formed when lead salts are added to blood serum is a complex lead salt containing phosphate, calcium and chloride. Because the exact nature of the insoluble salt of lead is not known, the calculations of Sobel and his collaborators about the solubility of lead phosphate, which they offered as an explanation of their observations, certainly are premature.

Our experiments show that the beneficial effect of calcium in the diet in retarding the retention of lead by the body is due to reactions which occur in the intestinal tract. Presumably lead is rendered insoluble and the extent of this reaction is governed under ordinary conditions by the concentration of calcium and not by the concentration of phosphate. The calcium in the present experiments was provided in the form of calcium carbonate and it is possible that some lead is precipitated in the intestinal tract as the carbonate, either alone or in the form of some complex salt. It has been shown¹⁸ that the lead of potable water can be quantitatively removed by passing the water through a mixture of calcium carbonate and magnesium oxide. Further experiments therefore will be necessary to show whether or not the calcium of milk is as useful as the calcium of calcium carbonate in retarding the accumulation of lead in the body. At the present time the evidence that milk would be of value is largely presumptive.

Dietary factors other than calcium and possibly vitamin D may be important in preventing the storage of lead. Shields and his collaborators¹⁹ have shown that the inclusion of considerable amounts of apple in the diet results in the retention of appreciably less lead in the bodies of experimental rats. These authors suggested that the pectic substances in the apple may be responsible for the beneficial effect. They observed that a solution of pectic acid, prepared from pectin by mild alkaline hydrolysis followed by acidification with acetic acid, precipitates even small amounts of lead. Other dietary substances such as fat²⁰ may be concerned with the biochemical behavior of lead in the body. The prevention of absorption by dietary means would thus appear to be worthy of further study as a means of prophylaxis against the accumulation of lead in the body.

CONCLUSIONS

It is concluded from the present studies made with young albino rats that the amount of lead stored in the body is diminished by the addition of calcium carbonate to the diet. The addition of phosphate has no significant effect. In harmony with other reports lead is found to be stored chiefly in the bones, and the kidneys are found to contain relatively high concentrations as compared with the liver. The beneficial effect of calcium appears to be due to the prevention of absorption of lead from the intestinal tract, because the calcium content of the diet has no significant effect on the retention of lead which is administered by injection into the abdominal cavity.

SATURDAY, JUNE 22, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

THE 1940 SESSION

New York City became the medical capital of the world early in June when the first advance guard of physicians began to register at the various hotels for attendance on a number of meetings of special societies which usually are held just before the annual session of the American Medical Association. With each day more and more physicians, accompanied frequently by members of their families, poured into the city. By Friday June 14, 12,864 physicians had registered their attendance on the annual session, exceeding by more than 2,500 the largest number ever previously registered in any session. The largest previously was the Atlantic City session at which the Canadian physicians also were in attendance. Physicians filled the lobbies of the hotels, thronged the scientific exhibits, were interviewed by one exhibitor after another in the Technical Exhibits, collected vast amounts of information and samples, applauded the Governor and the Mayor of New York at the opening session, participated in innumerable

social events, theater parties and radio broadcasts, and found time for an occasional hour at the World's Fair. Replete with information and entertainment and somewhat exhausted by the drive necessary to get the most out of a meeting of this kind, they began to depart toward the end of the week, expressing universal satisfaction in what they had gained at the meeting.

The problems that concerned the House of Delegates at this annual session were solved with a perspicacity and unanimity that were in themselves remarkable and yet indicative of the manner in which the medical profession is united today in solving its problems. Most significant was unquestionably the action taken with regard to medical preparedness. The Committee on Medical Preparedness was formed, including ten members of the House of Delegates and five officials of the Association, and is already in action trying to do all that the medical profession can do to place our country in a position to resist any aggression that may come upon us. Elsewhere in this issue appears a new section of THE JOURNAL entitled "Medical Preparedness," in which it is proposed from week to week to publish the actions of this committee and also such official announcements as may come from the Surgeon Generals of the United States Army, Navy and Public Health Service as well as from any other governmental agency requiring medical cooperation for medical preparedness. The minutes of the session as they are published in THE JOURNAL, will make clear the important actions taken by the House of Delegates.

The new officers elected include the President-Elect, Dr. Frank H. Lahey (described in an editorial comment in this issue), and a new trustee to succeed the late Dr. Charles Benjamin Wright; namely, Dr. William F. Braasch of Rochester, Minn. San Francisco was chosen as the place of the annual session of 1943.

On four floors of the Grand Central Palace the largest technical and scientific exhibits ever assembled were besieged by great numbers of physicians. Many of the technical exhibitors had prepared new installations of equipment especially for this occasion. A sympathetic gesture was the decision at the end of the session to present surplus supplies to the French War Relief. The Scientific Exhibits subsidized by the American Medical Association served a most useful purpose in graduate education; the individual exhibits surpassed in quality and in interest any similar collection available at any time in this country. Many a visitor to the annual session feels that he gains the utmost in graduate education from these exhibits.

The opening meeting of the annual session was held in the Grand Ballroom of the Waldorf-Astoria. This magnificent hall was packed to the doors and hundreds stood throughout the meeting. The Doctors' Symphony Orchestra, composed of physicians and related professional workers of New York, gave a demonstration of musical competence equal to that of many of the best professional aggregations. The Governor of New York:

brought the audience to its feet with a stirring appeal for medical cooperation in the maintenance of our democracy and told the assembled physicians that they were the ones to solve the problems of medical care for the American people. The Mayor of New York City, who had flown from Ottawa specifically for this occasion, told of his admiration for medical service and invited the physicians in attendance to visit the medical institutions of New York. The general sessions of the Association, the round-table conferences and all the meetings of the various sections were heavily attended, and the discussions were exceptional.

In the arrangements for the annual session of 1940 the Medical Society of the County of New York and the Medical Society of the State of New York gave complete and valuable cooperation. The radio program from this annual session was the largest ever attempted, including numerous broadcasts from local stations as well as on the national chains. The newspapers of New York, overwhelmed by the news of the war, nevertheless gave pages on some days and many columns on others to the news of the annual session. No doubt the success of this great session will stimulate the authorities of New York City, the hotel owners and the Convention Bureau to set in motion the necessary steps to provide that great metropolis with a convention hall adequate to the needs of an annual session of this type. In attendance, in quality and in every other way, it set a mark for scientific meetings.

THE FETAL FUNCTION OF THE THYROID

The fetal function of the endocrine glands has presented interesting problems for the physiologists. Certainly these glands do not remain inactive, particularly toward the end of gestation, only to assume full function suddenly at the moment of the infant's expulsion from the uterus. A number of water soluble substances may pass from the mother to the child, and vice versa. Maternal hormones reach the fetus, as demonstrated by the phenomenon of swollen mammary glands and the presence of so-called witch's milk in newborn infants of both sexes. The permeability of the placenta to at least some of the fetal hormones appears evident from several experiments. Carlson and Ginsburg¹ removed the pancreas from pregnant bitches that were almost at term and found that diabetes failed to develop until after delivery but occurred soon after. Apparently the fetal pancreas supplied the needed insulin. Pack and Barber² injected insulin into the fetuses of goats in utero and produced a decrease in the maternal blood sugar, thus demonstrating the permeability of the placenta to hormone transmission. Randall and Ryncarson³ found that newborn infants of diabetic mothers

presented not infrequently at the time of birth symptoms of hypoglycemia. They state that the metabolic condition in a pregnant woman with diabetes improves somewhat in the second half of pregnancy, presumably because of the activity of the fetal islands of Langerhans. After birth the child's pancreas continues to hypersecrete with resulting hypoglycemia. Ujiie⁴ found that partial removal in rabbits of the parathyroids or the thyroid resulted in an increase of the residual nitrogen and the amino acid fractions of blood nitrogen. These values persisted when the animals became pregnant during the first half of pregnancy but diminished in the course of the second half and returned to almost the values obtained before extirpation. This was interpreted by assuming that the accumulation of non-coagulable nitrogen in the blood took place as the result of extirpation and altered metabolism, and that during the second half of pregnancy the fetal parathyroids and the fetal thyroid supplied the mother with these hormones. These experiments seem to establish the permeability of the placenta to the parathyroid and thyroid hormones.

A striking clinical demonstration of the function of the fetal thyroid is offered by a clinical case reported by Zondek.⁵ He had the rare opportunity of following the development of idiopathic myxedema in a female patient for some years. The woman became pregnant after two years' treatment with thyroxine and gave birth to a normal child. During the first three months of pregnancy, symptoms did not appear; only the heart showed slight dilatation of the left ventricle, flattening of the PT deflection and lowering of the RS complex as the first indications of a beginning relapse. These changes became apparent during treatment with thyroxine and suggested that the pregnancy had an injurious effect on the maternal thyroid gland. At this point treatment with thyroxine was discontinued but contrary to expectation further symptoms did not appear up to the period after delivery. In the ninth month the basal metabolic rate was -1 per cent as compared with -29 per cent before the pregnancy and before the patient was given thyroxine. Shortly after delivery all the typical symptoms reappeared with "dramatic rapidity"—marked puffiness of the face, swelling of the eyelids, hands and feet, low and rough voice. Six weeks after delivery the basal metabolic rate was -29 per cent and the heart showed the typical alterations observed in myxedema. Thyroxine treatment once more effected improvement of all these symptoms. Zondek concludes that the sudden relapse after termination of pregnancy must be connected with the fact that the substituted activity of the fetal thyroid which had existed during the last months of pregnancy was no longer present.

FRANK HOWARD LAHEY—PRESIDENT-ELECT

Perhaps the greatest single attraction in the field of graduate education in the United States for a number of years has been Dr. Frank Howard Lahey of Boston, just elected to the position of President-Elect of the American Medical Association, shortly after passing his sixtieth birthday. He was born in Haverhill, Mass., on June 1, 1880, and received the degree of doctor of medicine from Harvard University in 1904. After his graduation he served as surgeon in the Long Island Hospital in 1904-1905 and in the Boston City Hospital, 1905-1907, and became resident surgeon of the Haymarket Square Relief Station in 1908 and instructor in surgery in Harvard Medical School, 1908-1909 and from 1912 to 1915. He was assistant professor and later professor of surgery in Tufts Medical School from 1913 to 1917. He also served as professor of clinical surgery in Harvard Medical School in 1923-1924. He has been for some time surgeon in chief of the New England Deaconess and New England Baptist Hospitals and Lahey Clinic. During the World War he served as major and also as director of surgery in Evacuation Hospital 30. He is a regent of the International College of Surgeons in Geneva, fellow and a member of the board of governors of the American College of Surgeons and a member of the American Surgical Association and the American Association for the Study of Goiter. His chief literary contribution, in addition to many periodical articles, is the Lahey Clinic number of the *Surgical Clinics of North America*. He has been a member of the editorial boards of *Surgery, Gynecology and Obstetrics* and of the *New England Journal of Medicine*. In the American Medical Association he was appointed by President Jabez N. Jackson at the Washington session in 1927 as a member of the Council on Scientific Assembly for a term of five years (to end in 1932); he was reappointed for a five year term (to end in 1937) by President E. H. Cary at the New Orleans session in 1932. He was appointed by President Irvin Abell at the San Francisco session in 1938 as a member of the Council on Medical Education and Hospitals for a term of seven

FRANK H. LAHEY, M.D.
PRESIDENT-ELECT OF THE AMERICAN MEDICAL ASSOCIATION

years and resigned following his election to the presidency. He was also a member of the Advisory Committee to Cooperate with the Bureau of Medical Economics of the American Medical Association Outlining the Necessary Procedure for Making Studies and Reports of the Prevailing Need for Medical and Preventive Medical Service (later called the Committee on Medical Care), which was established by the Board of Trustees at its February 1938 meeting. He was secretary of the Section on Surgery, 1926-1929, and chairman of the Section on Surgery, 1929-1930. It is doubtful that any other surgeon in the United States is more widely known to the medical profession throughout the nation than is Frank Howard Lahey. He has traveled widely and often and has given freely of his time for improving the quality of surgical diagnosis and procedure. He is a proficient speaker and will fill with distinction the new position of leadership which has just been given to him.

SAFE DRIVING AT NIGHT

Nineteen thousand two hundred persons were killed at night in motor vehicle accidents in the United States during 1938. Although less than one third of the total daily traffic was on the highways at night, 59 per cent of all fatal traffic accidents occurred during the hours of dusk and darkness. The amount of driving after drinking is higher at night and the hours of greatest fatigue are the hours of darkness; however, the Committee on Night Traffic Hazards of the National Safety Council in its 1939 report says that lowered visibility constitutes the major difference in the hazards of night and day driving. The committee points out how adequate visibility can be provided for safe night driving. Motorists should maintain their headlights in good condition. Head lamps can provide safe lighting for moderate speed if the lens is clean on both sides, if the bulb is not blackened, if the reflector is clean, and if all electrical connections are kept in proper condition so as to insure adequate voltage at the lamps; if the head lamps are aimed and focused correctly and if they are used properly; that is, if the upper beam is used when there are no approaching drivers and the lower beam is always used when approaching other drivers, and when driving on lighted highways or lighted city streets. Recent tests have shown, the

committee says, that the average head lamp on the road is producing less than half its possible light output because of tarnished reflectors, dirty lenses and blackened bulbs. The new "sealed beam" headlights appearing on most 1940 passenger cars are intended to provide higher light output in the driving beam for the open road and reduce the glare for the oncoming driver when the traffic beam is used. Most city streets still have the same type of lighting equipment that existed in the horse and buggy age; such lighting systems are wholly inadequate today from the point of view of traffic. The old types of illuminating emit light in all directions at about the same intensity. Illuminants today should be designed to capture the upward emitted light, the light directed toward private premises and the light that results in glare, and distribute it so as to produce uniform pavement brightness. In many places where improved lighting has been installed there has been a reduction in night accidents. In sixteen counties in New Jersey, for example, where modern safety lighting installations have been made, there was a reduction of 37 per cent in the night accident fatalities in the first eleven months of 1938 as compared with 1937. More data are needed to reveal the effect of different kinds of street lighting on accidents of various types. State and city authorities should make a scientific analysis of night accidents to determine the high accident areas and then study the visibility conditions to see whether there is adequate lighting for safe driving. Some cities mean to economize by waiting to turn on their street lights until it is quite dark. This must result in unnecessary accidents, for lighting is essential to the safety of both pedestrians and motorists. If any reduction in street lighting hours is made, it should be in the early morning hours of the summer when the streets are partly empty. In the early evening, when traffic is heaviest, such attempts at economy in street lighting should not be attempted. In many cities and towns a multiplicity of neon and other electrical signs in areas where traffic is controlled by stop and go signals has created a problem. More data are needed to reveal the effect of different kinds of street lighting on accidents. The Committee on Night Traffic Hazards of the National Safety Council proposes to make this study a major activity during the current year.

DR. CHEVALIER JACKSON RECEIVES DISTINGUISHED SERVICE MEDAL

Among the honors bestowed by the American Medical Association on its members who have won distinction, the one most carefully selected is the Distinguished Service Medal and Citation. Previous recipients have been Dr. Rudolph Matas of New Orleans and Dr. James B. Herrick of Chicago. The 1940 medal was bestowed on Dr. Chevalier Jackson of Philadelphia, known throughout the world as one of the greatest leaders in the field of otolaryngology and especially distinguished for his contributions to bronchoscopy. The physician who receives this medal is selected from

a great number of nominations which are made to the committee on this award. They send five nominations to the Board of Trustees, which in turn selects three names from the five; at the very opening of the House of Delegates one of these three is elected to receive the medal and citation. On this occasion the other two nominations presented to the House of Delegates were Dr. Ludvig Hektoen and Dr. James Ewing. The name of Dr. Chevalier Jackson was proposed also in 1939. Dr. Jackson, who because of illness was unable to attend the meeting to receive the medal in person, is now 74 years old. He received his degree of doctor of medicine from Jefferson Medical College in Philadelphia in 1886. He was professor of laryngology at the University of Pittsburgh from 1912 to 1916 and at Jefferson Medical College,

CHEVALIER JACKSON, M.D.
AWARDED DISTINGUISHED SERVICE MEDAL

Philadelphia, from 1916 to 1924, when he became professor of bronchoscopy and esophagoscopy at Jefferson and at the University of Pennsylvania Graduate School of Medicine. He held both positions until 1930. He retired recently as professor of clinical bronchoscopy at Temple University School of Medicine. His honors include fellowships in practically every leading organization devoted to his specialty throughout the world. He has been decorated by France, Belgium, Italy and Brazil. His writings include three books devoted to his specialty and innumerable contributions to systems of medicine and to surgery. He also received not long ago the Bok award from the city of Philadelphia, given to the resident who in the preceding year has "performed or brought to its culmination an act or contributed a service calculated to advance the best interests of the community."

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

COMMITTEE ON MEDICAL PREPAREDNESS

Dr. Irvin Abell, Louisville, Ky., Chairman
Dr. Charles A. Dukes, Oakland, Calif.
Dr. Roy W. Fouts, Omaha
Dr. Stanley H. Osborn, Hartford, Conn.
Dr. John H. O'Shea, Spokane, Wash.
Dr. James E. Paullin, Atlanta, Ga.
Dr. Walter G. Phippen, Salem, Mass.
Dr. Fred W. Rankin, Lexington, Ky.
Dr. Harvey B. Stone, Baltimore
Dr. Samuel E. Thompson, Kerryville, Texas

Ex Officio:

Dr. Arthur W. Booth, Elmira, N. Y., Chairman Board of Trustees
Dr. Austin A. Hayden, Chicago, Secretary Board of Trustees
Dr. Nathan B. Van Etten, New York, President American Medical Association
Dr. Olin West, Chicago, Secretary American Medical Association
Dr. Morris Fishbein, Chicago, Editor Journal of the American Medical Association

RESOLUTION ON MEDICAL PREPAREDNESS INTRODUCED BY DR. ARTHUR W. BOOTH, CHAIRMAN, FOR THE BOARD OF TRUSTEES

WHEREAS, The ravages of war again pervade many of the nations and peoples of the world; and

WHEREAS, The President of the United States has indicated to the nation and to the Congress the desirability of military preparedness so that our people may successfully resist attempts to substitute other forms of government for the democracy established by the Constitution of our country; and

WHEREAS, Organization of the nation for preparedness involves from the first the complete cooperation of the physicians of the country for

1. Medical services in the Military, Naval, Aviation and Veterans' administrations:

2. Selection of men physically fit to serve with such agencies; and

3. Rehabilitation of those not physically qualified to enable them to participate in military activities; and

WHEREAS, Preparedness demands also

1. Medical service to the industrial workers engaged in war industries;

2. Continuance of medical care of the civilian population;

3. Education of young men to qualify them for medical service; and

WHEREAS, The American Medical Association now embraces in its membership more than 117,000 of the licensed physicians of the United States; and

WHEREAS, The headquarters facilities of the American Medical Association has available

1. Complete records of all qualified physicians in this country, with data necessary to determine largely their availability for military or other services;

2. Complete information concerning facilities for education in medicine, the medical specialties and other medical activities;

3. Complete information concerning the hospitals of the United States;

4. The necessary facilities for making prompt contact through addressing devices, periodicals and constituent bodies with all medical personnel and medical agencies; and

WHEREAS, Only in the headquarters of the American Medical Association, as far as is known, are such information and facilities available; and

WHEREAS, The American Medical Association is not only the largest but also the only organization containing in its membership qualified physicians in every field of medical practice; and

WHEREAS, During the World War of 1914-1918 the American Medical Association aided in making available the services of more than 60,000 physicians for military and related activities; therefore, be it

Resolved, That the House of Delegates authorize the Board of Trustees to create a Committee on Medical Preparedness, to consist of seven members of this House, with the President of the Association, the Secretary of the Association, the Secretary of the Board of Trustees, and the Editor as ex officio members; and be it further

Resolved, That this committee establish and maintain contact and suitable relationship with all governmental agencies concerned with the prevention of disease and the care of the sick, in both civil and military aspects, so as to make available at the earliest possible moment every facility that the American Medical Association can offer for the health and safety of the American people and the maintenance of American democracy.

REPORT OF THE REFERENCE COMMITTEE UNANIMOUSLY ADOPTED BY THE HOUSE OF DELEGATES

Your committee is proud to see the patriotic tradition of the medical profession so well exemplified in this spontaneous and thorough resolution of our Board of Trustees. It is in strict accord with the history and traditions of the American Medical Association which has always been foremost in offering all its facilities and services to our government in times of stress or emergency. The committee has learned that through an unintentional omission the name of the chairman of the Board of Trustees was not included among the ex officio members and the method of appointing the members from the house was not specified.

We feel that the Chairman of the Board of Trustees should be included among the ex officio members and that the members selected from the House of Delegates should be appointed by the Speaker of the House of Delegates.

Your committee wholeheartedly approves this resolution and moves its adoption with the inclusion of these two changes.

FRANCIS F. BORZELL.	EDWARD M. PALLETTE.
JAMES R. McVAY.	J. DUFFY HANCOCK.
MCLAIN ROGERS.	EDWARD R. CUNIFFE.

ANNOUNCEMENT TO THE HOUSE OF DELEGATES BY COL. G. C. DUNHAM, U. S. ARMY MEDICAL CORPS

To the House of Delegates:

The following is a tentative plan for the procurement of professional personnel for the Medical Corps of the Army in the event of a national emergency. This plan has been prepared by the office of the Surgeon General of the Army and is submitted to the House of Delegates of the American Medical Association for its consideration.

1. The American Medical Association to be asked to conduct a survey of the medical profession through its state and local activities.

2. The local or county societies to canvass its members to determine, of those who express a willingness to serve, who should be available for the military service and who, on account of their age, physical disability or commitment in civil capacities should remain at home.

3. The county society to give to each one who expresses his willingness to serve, even though he may be selected to remain at home, a button similar to that which was designed for the Volunteer Medical Service Corps during the last war.

4. The county societies to list those who are selected for the military service according to their professional qualifications, listing as surgeons, psychiatrists, and so on, only those who are members in the national specialists' organizations. Also to select from those who are to remain at home, qualified men for examination boards.

5. The state societies to maintain an available roster of its members.

6. The American Medical Association to maintain a numerical roster of availability by states.

7. The Medical Department of the Army to have one or more selected officers on duty at headquarters, American Medical Association, in Chicago.

8. The War Department, Corps Areas or regional officers to call on the American Medical Association for physicians or specialists as and when required.

9. The American Medical Association to call on the states, according to their quotas, for the physicians required.

10. The state, in turn, to call on its local societies for its quota of physicians.

In the quotas, credits would be given for sponsored unity, and preference would be given to reserve officers wherever their qualifications warrant.

It appears that, in the event of a national emergency of great magnitude, it would be very necessary to conserve the medical profession. This plan would distribute the professional load and, if properly administered, should prevent the stripping of rural and isolated communities of their necessary medical personnel.

There could be an extension of this plan to cover the training program for technicians. The same societies could conduct a survey of the teaching institutions

to determine their availability and suitability for the training of such enlisted specialists as would be required. Rational medical service for civilian groups in war industries could be coordinated by the same administrative units.

REPORT OF THE REFERENCE COMMITTEE.

Your committee has carefully considered this resolution of Colonel Dunham's and is pleased to see such evidence of a desire for cooperation. We endorse the principles advocated but feel that the details should best be left to the committee established by the resolution of the Board of Trustees.

Your committee feels that in the choice of personnel every physician capable of rendering service be given opportunity to offer such services to our government and that in the selection of personnel for special services there be no arbitrary selection on the basis of organizations, or bodies thus far still in a developmental stage, but rather that membership in well recognized scientific specialty organizations, hospital appointments and similar qualifications be also considered for this purpose.

We therefore move that the thanks of the House be extended to Colonel Dunham and that the general principles of his resolution be endorsed.

EDWARD R. CUNIFFE.	JAMES R. McVAY.
J. DUFFY HANCOCK.	MCLAIN ROGERS.
FRANCIS F. BORZELL.	EDWARD M. PALLETTE.

SUPPLEMENTAL REPORT OF THE REFERENCE COMMITTEE

Information has come to the members of this committee that it is expedient to change one part of the resolution offered by the Board of Trustees and adopted by the House of Delegates last Tuesday. The ex officio members of the designated committee reside in New York and Chicago, leaving but seven members for the rest of this great country. Information from military authorities indicates that three additional members would be necessary to organize properly the United States. Therefore your committee recommends that that part of the resolution be changed to read as follows:

"Resolved, that the House of Delegates authorize the Board of Trustees to create a Committee on Medical Preparedness to consist of ten members of this House, with the President of the Association, the Chairman of the Board of Trustees, the Secretary of the Association, the Secretary of the Board of Trustees, and the Editor as ex officio members."

J. DUFFY HANCOCK.	EDWARD R. CUNIFFE.
JAMES R. McVAY.	

Under the terms of a resolution adopted by the House on Tuesday, and amended today, the Speaker of the House is directed to appoint ten members of a preparedness committee to serve with the five members named in the resolution.

The following members of the House are appointed: Stanley H. Osborn, Section on Preventive and Industrial Medicine and Public Health. Walter G. Phippen, Massachusetts. Harvey B. Stone, Maryland. James E. Paullin, Section on Practice of Medicine. Fred W. Rankin, Section on Surgery, General and Abdominal. Roy W. Fouts, Nebraska. S. E. Thompson, Texas. Charles A. Dukes, California. John H. O'Shea, Washington. Irvin Abell, Kentucky, General Chairman.

ORGANIZATION SECTION

PROCEEDINGS OF THE NEW YORK SESSION

MINUTES OF THE NINETY-FIRST ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD IN NEW YORK, JUNE 10-14, 1940

HOUSE OF DELEGATES

First Meeting—Monday Morning, June 10

The House of Delegates convened in the Jade Room of The Waldorf-Astoria and was called to order at 10:15 a. m. by the Speaker, Dr. H. H. Shoulders.

Preliminary Report of the Reference Committee on Credentials

A preliminary report of the Reference Committee on Credentials was submitted by the chairman, Dr. J. Newton Hunsberger, Pennsylvania, who reported that 137 delegates with proper credentials had registered.

Roll Call

The Secretary called the roll and announced that a quorum was present.

Distinguished Service Award

Dr. Arthur W. Booth, Chairman of the Board of Trustees, presented the following report:

The Committee on Distinguished Service Award of the American Medical Association submitted five names to the Board of Trustees. In accordance with chapter VI, section 5, of the By-Laws the Board has selected by ballot the following names for presentation to the House in alphabetical order: Dr. James Ewing, New York; Dr. Ludvig Hektoen, Chicago, and Dr. Chevalier Jackson, Philadelphia.

The Speaker appointed as tellers Drs. Samuel J. Kopetzky, New York; Harvey F. Garrison, Mississippi, and B. F. Cook, Vermont.

The tellers spread the ballot and the Secretary announced that 143 delegates had been reported present and that 140 votes had been cast, of which Dr. Chevalier Jackson received 61, Dr. James Ewing 54 and Dr. Ludvig Hektoen 25.

Since no nominee received a majority of the votes, the Speaker announced that another vote would have to be taken and that, in accordance with the rules, the name of the nominee receiving the smallest number of votes, namely, Dr. Ludvig Hektoen, would be dropped from the ballot.

The Secretary announced that 147 votes had been cast but that only 145 delegates had been reported registered, and the Speaker declared that there was no ballot.

Dr. J. Newton Hunsberger, Chairman, Reference Committee on Credentials, stated that 157 delegates had been registered, and the Secretary announced that 145 votes had been cast, of which Dr. Chevalier Jackson received 74 and Dr. James Ewing 71. The Speaker declared Dr. Chevalier Jackson, who received a majority of the votes cast, to be elected by the House to receive the Distinguished Service Award of the American Medical Association.

Adoption of Minutes of St. Louis Session

On motion of Dr. A. T. McCormack, Kentucky, seconded by Dr. Walter E. Vest, West Virginia, and carried, the House dispensed with the reading of the minutes and adopted the minutes as published.

Address of the Speaker, Dr. H. H. Shoulders

The Vice Speaker, Dr. R. W. Fouts, Omaha, presided while the Speaker, Dr. H. H. Shoulders, read his address, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker and Members of the House:

I wish, first, to express my appreciation of the honor and privilege of addressing you again as your presiding officer.

Second, I must say that I have no recommendations to make with regard to the procedure which has been followed for many years in transacting the business of the House.

It is my wish and intention to cooperate with you in the performance of our respective duties in such a way that the actions taken on all matters presented shall truly represent the deliberate and considered judgment of the House.

You are keenly aware of your responsibilities as the legislative branch of the government of a medical organization which is one of the greatest, if not the greatest, in the world. Your sense of responsibility in this connection needs no encouragement from me. Nor could I enhance your appreciation of the greatness of this Association.

It occurred to me that it might be worth while for us to consider for a moment at this time the qualities and attributes of this organization which make it great. Some would say our greatness is due to the fact that we have 116,266 members, the largest membership of any medical organization in the world. Another might mention a long list of scientific achievements to the credit of the organization. Still another might point to the many contributions made to increasing the skill and ability of the medical profession in serving humanity. It is true that the American Medical Association is the largest medical organization in the world. Its contributions to medical science have been nothing short of marvelous. It is also true that its contributions to the betterment of human welfare have been inestimable. In my humble judgment neither one of these accomplishments, nor all of them together, account for the greatness of this Association. We all know that mere bigness has never made an organization great. We know that scientific achievements alone do not make an organization really great. We know also that contributions to advancement in the art of medicine do not make this organization great. These contributions and accomplishments are evidences of greatness but they do not explain the achievement of greatness.

We have seen human organizations composed of large numbers disintegrate and disappear. We have witnessed and are still witnessing, at the present time, something of the disaster which results from the application of scientific knowledge to very destructive ends. We know that scientific advancement in any field, when not guided and directed by a high order of ethical principles, may, and often does, bring about tragic consequences. This is especially true in the field of medicine. The consequences of such a situation, may, in fact, be more tragic than if the scientific advancement had never been made.

In our search for the qualities and attributes which are responsible for the greatness of this organization we must look backward a bit and underneath these evidences of greatness.

The following simple statement is found in the constitution of this organization: "The objects of the Association are to

promote the science and art of medicine and the betterment of public health." Those who wrote and adopted that phrase as a statement of purpose must have had something of the philosophy of service expressed by the Great Physician. But the mere adoption of such a statement does not suffice to account for greatness. We have witnessed on many occasions the adoption of noble statements of purpose by organizations scientific, political and otherwise. We have also witnessed the repudiation of these statements by acts soon after their adoption.

The extent to which this statement of purpose has permeated the organization and motivated its actions determines the measure of its influence in accounting for greatness: Reference to actions of the House on many occasions and on many issues will reveal that the spirit of the statement has been ever present.

A long time ago this House of Delegates adopted a code of ethical principles. That document, in my opinion, deserves a place in our reverence alongside the Declaration of Independence and the Constitution of the United States. Its provisions were wisely designed to accomplish a noble purpose. They were not intended to promote and protect the financial interests of individual doctors and they have never so operated. Their observance has never hindered scientific progress nor have they hindered the application of the science and art of medicine to the needs of humanity. The complete opposite is true. They have promoted the science and art of medicine and, what is more, they have operated in such a way as to make this progress safe. They have promoted the legitimate use and prevented the dangerous abuse of scientific advancement in the field of medicine. It is a fact that financial benefit to individual doctors results from the violation of these principles, not from their observance. In the same way injury comes to the public.

We find also that the spirit of democracy was breathed into the vitals of this organization at the very beginning of its life. That spirit, too, has remained. When the matter of freedom is touched by any issue raised in this House, your concern becomes alert at once, not for the freedom of doctors, but for the freedom of patients. You have, in fact, displayed more concern for the freedom of patients than you have for the freedom of doctors.

It is insisted at times that, if these principles were destroyed, professional progress would be augmented; that, if patients and doctors alike were subjected to the direction of some powerful individual or government agency, all the faults and defects in the present system of medical care would disappear and all would be perfect. We are the first to admit that, if all these directing and restraining influences were destroyed and all our activities and attitudes were determined and directed by a single individual or agency, a far different situation would be brought about. First, it would make of this organization a far more potent political force. Actions could be reversed overnight if political expediency seemed to demand. Convictions would be submerged and rendered impotent. It would make of us a streamlined political outfit, but no one could predict what the ultimate consequences would be. Under our existing rules of procedure, guided as we are by the influences referred to, we are in position to take a long range view of every situation. We are in position to consider not only the immediate but the remote effects of every new development. We are in position to make the kind of progress in the science and art of medicine that is safe. And, what is more, by preserving these principles we contribute to the preservation of that priceless heritage of freedom for all.

These are the attributes which, in my opinion, have made our organization great. To this House of Delegates has been committed the task of judging and preserving the qualities and attributes which deserve to live.

In Memoriam

This House of Delegates very appropriately established the custom of taking official notice of the death of Fellows who have served the Association in official capacities, either as members of the House or as officers of the Association.

Pursuant to this custom it now becomes the melancholy duty of the Speaker to call the roll of those who have passed into the Great Beyond since we met last May:

James H. Borrell, New York, 1937-1939.
Perry Bromberg, Tennessee, 1913-1915; 1917.
J. Forrest Burnham, Massachusetts, 1915; 1919-1934; 1935 special session; 1935-1936.
John M. Cooley, Pennsylvania, 1923.
Arthur E. Crow, Pennsylvania, 1925-1927.
H. A. Davidson, Kentucky, 1923; 1926-1927.
Robert V. Day, California, 1925-1926.
Thomas D. Doan, Illinois, 1918.
Charles A. Elliott, Chicago, Vice President, 1927-1928.
Alexander C. Ewing, Utah, 1903.
Charles Falkowsky Jr., Pennsylvania, 1936; 1938; 1938 special session; 1939.
Thomas P. Farmer, New York, 1933-1934; 1935 special session; 1935; 1937; 1938; 1938 special session; 1939.
George M. Fisher, New York, 1923; 1927-1928; 1934-1937; 1938 special session; 1938-1939.
William D. Haggard, Tennessee, 1905-1906; Section on Surgery, General and Abdominal, 1922; President-Elect 1924-1925; President 1925-1926.
J. N. Hall, Colorado, 1903; 1906-1908; 1919-1921; Member Judicial Council 1921-1931.
J. F. Highsmith, North Carolina, 1907-1909; 1912; 1921-1922.
Walter A. Lane, Massachusetts, 1937.
William V. Laws, Arkansas, 1913-1914.
W. C. Leary, Massachusetts, 1934.
Arthur T. Legg, Boston, Section on Orthopedic Surgery, 1936.
J. P. Lord, Nebraska, 1921; 1925.
Charles H. Mayo, Rochester, Minn., President-Elect, 1916-1917; President, 1917-1918.
William J. Mayo, Rochester, Minn., President-Elect, 1905-1906; President, 1906-1907.
Alexius McGlannan, Maryland, 1915; 1917; 1930-1932.
L. H. A. Nickerson, Illinois, 1908-1909.
Lee Vallette Parmley, Arkansas, 1936.
Fred W. Powers, Iowa, 1905.
E. A. Pray, North Dakota, 1920; 1922-1923; 1925; 1927-1928.
S. C. Red, Texas, 1929.
James E. Sadlier, New York, 1909-1910; 1929-1932.
William B. Small, Iowa, 1917-1920.
Robert P. Smith, Maryland, 1905.
Martin L. Stevens, North Carolina, 1907; 1923-1934; 1935 special session; 1935-1936; 1938; 1938 special session; 1939.
Charles W. Stone, Ohio, 1931-1935 special session; 1935-1937; 1939.
D. D. Swearingin, New Mexico, 1919.
W. O. Sweek, Arizona, 1918; 1935 special session.
Frederick H. Thompson, Massachusetts, 1911-1912.
Vernon L. Treynor, Iowa, 1934-1935 special session; 1935-1937; 1938 special session; 1939.
F. E. Trotter, Hawaii, 1924; 1930.
Earl R. Whipple, Pennsylvania, 1930.
C. B. Wright, Minneapolis, 1930, 1931, 1932, 1933; Trustee from 1933 until the present.

This roll contains the names of illustrious men in medicine. They carried the banner of our profession and held it high. Their examples of service and sacrifice are still, and will ever be, an inspiration to us.

It is suggested, Mr. Speaker, that the House rise and remain standing for one minute as an affectionate tribute to their memory.

At the request of the Vice Speaker the members of the House arose and stood in silent tribute to the memory of departed delegates.

Reference Committees

The Speaker announced the personnel of the Reference Committees and, without objection from the House, included the personnel of a Reference Committee on Executive Session:

SECTIONS AND SECTION WORK

Stanley H. Osborn, Chairman, Section on Preventive and Industrial Medicine and Public Health
George Gray Ward.....Section on Obstetrics and Gynecology
Thomas F. Thornton.....Iowa
Samuel P. Mengel.....Pennsylvania
Joseph F. Smith.....Wisconsin

RULES AND ORDER OF BUSINESS

John H. O'Shea, Chairman.....Washington
William D. Johnson.....New York
Edmond F. Cody.....Massachusetts
Hilton S. Read.....New Jersey
E. H. Skinner.....Section on Radiology

MEDICAL EDUCATION

Harvey B. Stone, Chairman.....Maryland
Elbridge J. Best.....California
L. A. Buie.....Section on Gastro-Enterology and Proctology
C. E. Kiely.....Ohio
George Blumer.....Connecticut

LEGISLATION AND PUBLIC RELATIONS

F. S. Crockett, Chairman.....	Indiana
Charles J. Whalen.....	Illinois
L. G. Christian.....	Michigan
Wingate M. Johnson.....	North Carolina
Thomas A. McGoldrick.....	New York

HYGIENE AND PUBLIC HEALTH

E. S. Hamilton, Chairman.....	Illinois
W. F. Draper.....	United States Public Health Service
Karl S. J. Hohlen.....	Nebraska
Clyde L. Cummer.....	Section on Dermatology and Syphilology
Felix Underwood.....	Mississippi

AMENDMENTS TO CONSTITUTION AND BY-LAWS

David D. Scannell, Chairman.....	Massachusetts
William Weston.....	Section on Pediatrics
Barney J. Hein.....	Ohio
Charles A. Dukes.....	California
A. A. Walker.....	Alabama

REPORTS OF OFFICERS

Walter E. Vest, Chairman.....	West Virginia

Address of President Rock Sleyster

The Speaker resumed the chair and presented the President, Dr. Rock Sleyster, Wauwatosa, Wis., who delivered the following address, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker and Members of the House of Delegates:

Two years ago this House of Delegates placed with me a responsibility which could not be lightly assumed. With it came unusual opportunities for service, for observations and for study. I have tried to take every advantage of these opportunities so far as my strength would permit. During this period I have covered every section of our country and regret only that I was unable to accept all invitations extended to me. In thirty-seven years of work in organized medicine I have met medical men from all sections in their own homes, in their own meetings and in their own fields of work and I have been able to discuss with them their individual problems. This has been a pleasant and a profitable experience. I hope these visits have been helpful to others as they have been to me, and I want you to know of my deep appreciation of this opportunity to serve. It is customary for your retiring President to record some impressions gained during his tenure of office.

SOLIDARITY

First I want to comment on a truly united profession. There are those who have tried through the creation of some small self-constituted groups and committees to create the impression

that the medical profession is seriously divided. This is not true! Purely local conditions do influence thinking; as the result of the serious determination to meet local responsibility, certain plans may be at variance with those found elsewhere. This is natural and to be expected. Almost to a man, however, I have found a solidarity of the medical profession. I have found everywhere an enthusiastic loyalty to the American Medical Association. I have found a singleness of purpose in maintaining the policies determined by this House of Delegates—their democratically constituted representative body. The report of the Secretary confirms this observation. A gain of 3,171 was recorded in forty-six constituent associations for the year ended March 1, 1940. During the past five years—years during which the organization was subjected to every attack ranging from vicious propaganda to actual indictment—the membership of the American Medical Association was increased by the entirely voluntary enlistment of more than 15,000 new members anxious to participate in the defense of medical standards, medical advances and the public health. This is our answer to propaganda designed to create the impression that ours is not a united group.

INTEREST

One cannot go about the United States without being impressed with the growth of interest in medical science and affairs. I have addressed lay meetings conducted by lay organizations with an attendance of more than fifteen hundred. I have addressed meetings of rural county societies with an attendance of nearly half the state membership, many of the members having driven more than a hundred miles to attend. Everywhere I have been impressed with the sincerity and earnestness of purpose of medical men to measure up to every responsibility in meeting problems related to making available the highest quality of medical service regardless of material reward. Everywhere I have been impressed with the desire to secure the benefits of all that is new in scientific advance. Never at any time, in any place, have I heard an expression of selfishness. The one great question has been "How may we better defend and preserve unimpaired American medicine in its present preeminent position—how may we better serve those who place their confidence in us?" I cannot refrain from commenting at this point on the American medical man as I have found him in his own community. I have always held him in highest esteem, but more than ever I admire his fine qualities of heart and mind. I know of no group with higher ideals or with greater unselfishness. I am proud of him, of all he stands for, and of his record of accomplishment.

WORK OF THE ASSOCIATION

In addressing you at St. Louis last year I called attention to the danger to the primary purposes of the American Medical Association found in the pressure of economic and political attack. It is to be regretted that an organization which through the years has been able to devote all of its resources, energy and thought to the advancement of science and improvement in its application should in any degree be diverted from its primary purpose in order to defend a record so outstanding. It is heartening to note that, in spite of all this interference, the work of the headquarters, the Councils, the Bureaus and publications has gone on with increasing efficiency and with increased demands for their service. These departments stand for ideals you have created. They are establishing standards you have set. They are making attacks you have directed. We are proud of the reforms they have brought about. But they are subject now, as in the past, to insidious counterattack by selfish interests both in and out of the profession. To them you owe a paternal defense and loyalty. This can be given only by a greater familiarity with their historical background and a better knowledge of their purposes and functions. It requires an understanding of the reasons for what are often innocent appearing movements, movements which may enlist even well intentioned members but which, if carried through, will take from these bodies functions which you do not wish placed with small, interested and self-appointed groups responsible to no one. The observation I most regret to report is the ignorance I have found everywhere regarding the activities of the Association. I wish it were possible that during

the coming year every component society could give over one meeting to an illustrated program bringing home to its members the activities and the policies of this Association. Speakers for such a venture could obviously not be furnished by our headquarters but they could be developed by each state society. A team could be selected and sent to our headquarters for necessary information and inspiration. Illustrative material could be provided. I know of no expenditure which would yield richer returns.

PREPAREDNESS

When the United States entered the World War the American Medical Association offered its services to the federal government in every capacity. More than 200,000 blanks for regular application for commissions in the Medical Reserve Corps were printed by the Association and circulated among physicians. As a result, more than 30,000 applicants were commissioned in the Army and, in addition, more than 3,000 in the Navy.

The American Medical Association acted as a center of information for physicians and sent out hundreds of letters each week in response to inquiries regarding the Army, the Navy, the Public Health and the Civilian Service. More than 5,000 pamphlets were printed by this office giving information regarding entrance into the Medical Corps. State and county organizations were supplied with detailed information concerning the work of physicians in their own communities and with those available for civil and industrial practice.

Early in the war the Association cooperated with the Provost Marshal General in relationship to the medical aspects of the selective service. The House of Delegates itself selected a special war committee to obtain information and to cooperate with all agencies in fulfilling to the utmost the medical needs of the organization.

At the time the Armistice was signed there were 35,000 medical officers in the Army and 3,000 in the Navy, which alone represented about 26 per cent of the entire medical profession of the country. Moreover the mobilization of the medical profession was based on utilization of the county and state medical societies which constitute the American Medical Association. Equally significant was the work of the physicians on the local draft boards, who provided our Army with men physically fit to accomplish the magnificent work which was accomplished in the World War.

At that time the mobilization of the industrial forces and the health of the nation and the protection of both the nation and its armies were regarded of such importance as to demand direct representation of the medical profession on the government board for national defense.

During the war the ratio of medical officers killed and dying of wounds was exceeded only by that of the infantry and artillery.

Today our nation is again preparing to defend itself to the utmost against any type of aggression from without. The medical profession, through its House of Delegates, I know, will pledge itself to give, as it has always given in the past, every iota of service that it is capable of rendering, and I would call on this House of Delegates to prepare, in suitable form, an offer of this type to the federal government.

PUBLIC RELATIONS

Today marks the opening of the annual session of an organization which has gathered each year for nearly a century from the four corners of this great country for the sole purpose of improving its service to the sick. What a contrast to a world gone mad in its efforts to take human life—a world exhausting its resources in preparing means of destruction! During the last half century the progress of science, and the art of its application in a country which has kept it free and unfettered from political interference, have brought blessings never before enjoyed by any people. Free men, unworried by restrictions, devotedly probing the unknown causes of suffering, have developed and applied knowledge which in the century past has doubled the life expectancy of man, has conquered many of the scourges, has produced specific treatment for

diseases formerly hopeless and has given the American people the highest standards of health the world has ever known.

All this has been coincidental with and because of the adoption and development by our nation, when first founded, of a political philosophy that government exists for its people instead of the people for government. Government was to protect individual freedom and expression, not to restrict it. Government was to make men free, to do away with fear, to encourage self reliance, to remove barriers to thought, to stimulate imagination and to secure rewards for sacrifice and effort. In this security, with this freedom from interference, science in all its branches has made progress in our lifetime beyond the wildest dreams of even a Jules Verne. No branch of science, however, has brought blessings to humanity comparable to those which can be credited to the progress of medicine.

During the last decade we have seen abroad the reversal of the gradual trend toward development of the individual. Each year there has been more and more encroachment on freedom of thought and opportunity of expression. Opportunists, playing on the emotions of people in distress, have gradually brought about a return of restrictions and regimentations which progress through the century had gradually reduced. Through fear and false promises of security, individual liberty has been surrendered. Centralization of power, with its inherent greed under dictatorship, is destroying the moral and the economic, scientific and spiritual values of the world. The survival of civilization is threatened. We have but to make simple comparison with records abroad to determine the disastrous effect on health and medical progress. As government regulation and interference increased, progress was stifled and regression was immediate.

In all this world only America stands out today as enjoying a freedom of thought and action which can carry on. Even here we note with growing concern certain trends toward centralization of power—trends which are placing under political regulation more and more lines of human effort. No informed and thoughtful person can deny the threat to medical progress and to the public health in some of the proposed legislation in Washington. If enacted as introduced it would represent an advance in restrictive regulation which would parallel the disastrous developments abroad. The results could not be different from those we have been led to expect through experience.

We come now to the universal question "What is the answer to the problems which confront us?" I have no answer. I know of no one magic word which will unlock the doors to the future and make easy a solution of problems which baffle the world. Of this I am certain: The problems we are called on to solve are only a part of a whole. They should not be singled out for radical treatment and experimentation. They are end results of economic failures of a world gone mad with greed—failures which have left their ugly mark on every walk of life. We are not to be blamed for their origin. No treatment can be efficacious which disregards cause and fails to treat the patient as a whole. No legislation which seeks to care for end results, by ignoring fundamentals, can furnish any adequate answer to the problem of medical care. It is not as simple as all this.

We do not deny a responsibility of government for the health of its people. The history of this Association is a record of continued effort to make government conscious of this duty. The great health movements of this country were initiated, fostered and promoted by the medical profession. We believe, however, that the proper function of government under a democratic system is the protection of its people from hazards to health, the promotion of standards of living which are favorable to health, and leaving to a free people the free choice of medical care when illness comes unless indigence prevents. We believe that the most profitable expenditure of government effort and means in the cause of the sick would be attained, as it has been in the past, through efforts toward the prevention of disease. Let government fight disease at its source as it should; protect the well from the hazards of contact; insure a mode of living which supplies the requirements of proper food and adequate clothing; eliminate the hazards of slum and tenement; provide proper housing; offer wholesome recreation; instruct the masses to avoid the dangers which go with igno-

rance; educate them to take advantage promptly and intelligently of means now available when threatened with illness, and protect them from the appalling toll of senseless and unnecessary accidents. Let government concentrate its every effort on these sources of mortality and morbidity, and the cause of health, life and happiness will be advanced countless times more than it can be furthered by placing the sick under any form of political control.

The American Medical Association stands almost alone in defense of a historic system of freedom of science and its application for human welfare—a system which shows with pride a record unrivaled in the benefits it has brought to humanity. At this session let us rededicate ourselves to a defense of those principles and policies so necessary to preserve the accomplishments of the past, so necessary to guarantee progress in the future.

Address of President-Elect Nathan B. Van Etten

The Speaker presented the President-Elect, Dr. Nathan B. Van Etten, New York, who delivered the following address, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker and Members of the House of Delegates:

The last time the American Medical Association honored New York was in 1917, when the country was involved in the World War, which enlisted the medical profession in a selective draft, in military training, in military hospitals here and abroad and in active service on the field of battle.

Again the horrors of fratricide of even wider dimensions stir our emotions; again the uncertainties of the continuation of our civilization present a confusing prospect. After long preparation of a new generation of people, through education in paganistic ideologies, intolerance, persecution and brutal expulsion of nonconformists; after reversions from limited democracies to autocracies of the most violent types the pagans are marching, destroying peaceful homes and murdering innocent civilian neutrals in an effort to gain world domination. Again the medical profession in America is being mobilized to defend our liberal democracy against the invasion of foreign influences.

If paganism is successful in the European theater, its influence will be spherical and strong resistance must be organized in the United States. Although our borders may not be crossed, the subversive influence of so-called "fifth columns," already here, will grow stronger in our national administration and we may be compelled to follow dictation which may destroy the practice of medicine as we know it and as we hoped it might become. The American Medical Association has already offered all of its organizational facilities to the federal government and stands ready to cooperate to the limit of its ability in all measures of national defense. If we must enter a new war as combatants, we shall do so whole heartedly.

Love of country is a noble passion, but loss of the strong position of organized medicine in the United States would be deplorable and in the midst of this excited moment we must not lose sight of our patriotic ideals for the health and happiness of our people. We must not lose sight of the dangers to medical practice through concentrations of federal authority. Regimentation is a word which has been so greatly overworked that we shrink from its frequent use. We do not like the sound of totalitarianism. The thought of dictatorship in America is revolting. And yet appeals to popular emotion under theegis of patriotism, of social security, of pensions, of welfare, of relief of unemployment or of the people's health have carried many people from confidence in their ability to take care of themselves to belief that they have no personal responsibility for providing the sources of paternalism which they expect to enjoy. They believe that they will drink forever from the inexhaustible well springs of government. Dictatorships are built on such public sentiment. If such sentiments prevail, the medical profession may well expect a fate similar to that which developed in Germany and reduced the physician to a very low place in the social scale.

Compulsory health insurance was advocated here in 1917 and has been assiduously pushed by some welfare organizations which would have been obliged to close their doors long ago except for the generous support of the medical profession. Organized medicine has successfully prevented the legal establishment of any of these foreign systems, but the skeletal fabric has been erected in the systems of temporary emergency relief administrations and must be closely watched by all physicians lest they awaken some day to a realization that they have been regimented while they slept.

The President's plan for medical service through small hospitals in places where they are needed is in harmony with the platform of the American Medical Association and should be supported by the medical profession. There are, however, those who see in this part of the government program merely one foot in a door opening toward the development of the health program proposed by Senator Wagner in his original bill, S. 1620. This opinion is supported by Senator Murray's statement in reporting the modified Wagner-George bill 3230, when he said "Your committee recognizes that the situation of the health problems which have received its attention for several months." I believe, however, that we should, along with the President in this matter and favor the building of small hospitals and additions to existing hospitals where the need for them can be proved.

There are physicians who approve the President's plans in principle and in many details but who feel that it may be easy to enlarge the meaning of these hospitals to include all sorts of collateral construction that will absorb considerably more money than the ten millions which may be appropriated for the first year. Already the committee seems to be thinking in terms of elaborate diagnostic centers and seems to expect the government, rather than the local profession, to run them, when all that is really needed is clean, warm places for the care of the acutely sick by competent personnel. Small communities cannot usually support specialists. Small community hospitals can be considered as workshops for ordinary physicians sufficiently educated to take care of average patients who will make up the average tenantry of these institutions, these hospitals may satisfy a real need. For patients needing more expert care, would not ambulance service to carry them to larger hospitals in larger towns solve their problems in a better way than by trying to maintain experts in small places? Building elaborate hospitals in places where they cannot be supported or served locally will only waste money. Planting subsidized physicians in such places would not seem to inspire confidence in their ability to give competent service. Bringing medical care closer to people who may need it is admirable, but all phases of the question need careful study.

When Herman Biggs was health commissioner of the state of New York he proposed building cottage hospitals and laboratories in order to solve the rural problem. At a hearing before Governor Smith everybody seemed to favor the project. Finally the governor said he would like to hear what some country doctor thought about it and a doctor from Malone, away up in the Adirondacks, rose and said "In the summer time the Adirondacks are full of city people and there are plenty of city doctors to take care of them, but in winter very few people are there and the country doctors and the small towns have plenty of facilities to care for them. All we ask you to do, Governor, is to keep the roads open." The cottage hospitals were not built. Good roads in the state of New York solved the rural problem. There is now a physician within thirty minutes of every person in the state.

The health needs of the people are the concern of the medical profession and must be discovered and remedied by physicians, many of whom have been prone to wait for lay people to demand new services before they responded to an obvious need. The result is that the medical profession is constantly attacked by those who are playing political games and looking for public approval and salaried jobs. This situation should be reversed. The physician should direct local efforts in community health. A community that has no health program is

culpably negligent and so are the physicians who permit such service failure. There seems to be confusion over the question of real needs. What and where are they? The Council on Medical Education and Hospitals has made surveys of hospital needs in every state and its surveys do not justify the claims of those who are supposed to represent the people in public places. Are the Council's surveys correct? Might it not be worth while for every delegate to carry home the Council's appraisal of the health needs of his state and examine every county and community of his state from local points of view and ascertain for himself wherein the Council's figures differ from the factual data which he may be able to discover? The delegate who does not know local needs is not a fully qualified representative. If he cannot bring to this body an accurate picture which will justify intelligent action on national health problems his failure discredits the final judgment of this policy making group.

I would like to ask each delegate a few questions: Does your state need more hospitals in new locations? Does your state need more beds in existing hospitals? Does your state need more laboratories? Does your state need more ambulances? Does your state need and can it support more doctors? Does your state need more specialists? Does your state need more public health nurses? Does your state need more welfare workers? Does the health program in your state need financial help through federal agencies from the general tax pool? Have you read the Wagner health bill, S. 1620? Have you read the Mead bill? Have you read the Pfeiffer bill? Have you read the modified Wagner-George bill? Have you studied the President's plan? Do you know the American Medical Association's platform by heart? And do you understand its implications? Do you know Surgeon General Par-ran's plan for a crusade against syphilis? Have you thought about the possible effect of government interference on your own private practice? Does the medical service in your state serve your citizens adequately? Among other states New Jersey gives the following answer: "Within the scope of any reasonable definition of the term [adequacy] the facilities and their distribution in this state are adequate. Lack of acceptance of these facilities is the only reason for any person in this state not receiving medical care." Can you say the same for your state?

Once more may I remind you gentlemen of the House that you are the most powerful officers of organized medicine: that every one of you has been chosen to represent the physicians of your states and that on you rests a heavy responsibility at all times, and especially at a time when not only the practice of medicine as you know it but the problem of the future health of all our people is being attacked by amateur health philosophers who know nothing about the personal practice of medicine and who know about mass medicine only from superficial observation of foreign systems none of which have improved the quality of medical service or have produced anything superior to our present system in the United States in 1940.

None of you can claim perfection for our system of delivering medical service, but all of you know that the American Medical Association has been working for ninety-three years to improve it, that its chief concern is better health for all our people and that nowhere on earth have better results been attained.

Last year in St. Louis you developed a program for medicine which your Trustees translated into an eight point platform. The first point was the advocacy of coordination of federal health functions under one agency. This question has long been debated without result. In the January issue of *California and Western Medicine* it is stated that Dr. Thomas M. Logan proposed a national health department in 1871. I quote his words: "Let us have a Secretary of Health, as well as a Secretary of War. The achievement of this great national undertaking, as of every other great and good work among men, can only be effected by time and patience, by rational inquiry and enlightened persistence."

In 1875 the House of Delegates asked for a Secretary of Health in the cabinet of the President. A renewal of this desire for a coordination of health functions has met with the favor of many people within the profession and in public life. Representative Pfeiffer introduced a bill "To establish a Department of Health" on March 6, 1939. It was referred to the Committee on Expenditures in the Executive Department, where it still reposes. Hon. Paul McNutt advocates it strongly and plenty of support can be gained if the physicians of the country really desire it. If city health departments have proved indispensable, if state health departments have proved valuable, why has a national health department been so long postponed?

I believe that it is an important defensive measure and that it is timely to attack the problem with confidence in a successful issue.

I believe that it is a sane procedure for developing an intelligent correlation of national health problems.

I believe that erecting a national health department may be one way toward bringing the good offices of the government into concert with the ideals of the American Medical Association's platform.

I believe that the medical profession should go along with the government as far as possible for the common good without sacrificing its individual interests in the care of the sick and its collective interests in the prevention of disease.

I believe that the medical profession by tradition and by education is highly qualified to stimulate and sustain the morale of our people in times of crisis, when pagan ideologies are undermining and destroying high ideals. We must not minimize the seriousness of the present moment. Distance may ensure temporary safety, but disruption of our society is imminent.

If we have any religion, if we have faith in God and our fellow men, now is the time to cherish it and to fight for it with confidence that we shall prevail.

Address of Vice President Alphonse McMahon

The Speaker presented the Vice President, Dr. Alphonse McMahon, St. Louis, Mo., who addressed the House as follows:

Mr. Speaker, Members of the House of Delegates:

I have prepared no formal speech for this morning, for which fact I am sure you are quite happy. I do want to take this opportunity, however, to thank the House of Delegates for the honor accorded to the St. Louis Medical Society in electing one of its members to this office. I also want to thank the House for the pleasure given to me in the past year of being permitted to attend some of the activities of this great Association. Through this contact, I have learned something of the tremendous duties and responsibilities devolving on your officers. I want to thank these officers and the members of the Board of Trustees for the privileges accorded me in attending the sessions and also for the many courtesies extended to me in the past year. Thank you very much!

Address of Dr. T. C. Routley

On request of the Speaker, the Secretary presented to the House Dr. T. C. Routley, Official Representative of the Canadian Medical Association, who addressed the House as follows:

Mr. Speaker, Mr. President, Mr. President-Elect, Gentlemen:

I naturally am deeply touched by the warmth and cordiality of your welcome. For a period now of seventeen years you have been receiving me on my perennial visits, and on each occasion I have gone away feeling that I loved you more. You took me into your hearts and your homes and I have felt that I was amongst good friends.

Last night when I crossed from Canada to the United States only two incidents occurred which made me conscious of the fact that I was leaving my native land to proceed to that of a friendly neighbor. In the first instance, a most courteous young gentleman came to my compartment and told me that he was

the immigration officer. He asked me who I was and where I was going. He took time to sit down to tell me how welcome I would be in the United States.

The next caller was the customs man, who asked me how much hard liquor I had and one or two other similarly pleasant questions and assured me, too, that I would be most welcome in this country.

Mr. Speaker, I would ask you, sir, and ladies and gentlemen, to contrast that episode with what is taking place in other parts of the world today. I think, sir, that these two countries and this continent still have a great opportunity to demonstrate to the world what friendly neighbors can be to one another.

It is now my very pleasant duty to bring you cordial greetings from the Canadian Medical Association, which I have the honor to represent as its General Secretary. Our association is holding its seventy-first annual meeting in Toronto next week, and I am charged to say to you that every member and colleague of the American Medical Association who finds it convenient to come to Toronto will be most welcome indeed to all of the facilities and everything that we have to offer you in that city.

Since I saw you last we have had to take on a new job in Canada and, if you will forgive me for trespassing on your time for a moment or two longer, perhaps you would allow me to say this: When our country entered the war, our association did just what you would do here under like conditions. We told the government that we were prepared to assist. Within three days we had mobilized the medical profession of Canada. Ninety per cent of our profession volunteered their services, and of these 90 per cent volunteered to go anywhere or do anything that might be required. What we have attempted to do as a medical association is to put round pegs in round holes, and we are able to guarantee to our country that, no matter what the exigencies may be, we shall be able to provide medical personnel for all emergencies and all services, and indeed, sir, if there is any person in this room whom I had the good fortune to meet in England some twenty-three or twenty-four years ago, I would be most happy to meet him again. When your country entered the war, you sent across an advance guard of doctors and engineers. Some fifty of these doctors came down to Salisbury Plain, and as I was the only Canadian in that British army at that moment, I was charged with the responsibility of taking these men in tow and telling them something about forming fours and saluting.

You will recall that in those days doctors were supposed to know nothing about war. Many of us found out a lot about it before we were through. If any of those men happen to be here, I should greatly esteem it a privilege to meet them once again.

Mr. Chairman, let me say again I greet you, I salute you, and I trust as friendly neighbors we may always go on demonstrating to this world just what it means to understand man's humanity to man.

THE SPEAKER: This expression by the House I am sure should not be supplemented by any remarks of mine. We welcome and appreciate your presence.

REPORTS OF OFFICERS

Report of the Secretary

Dr. Olin West presented his report as Secretary, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary, with the exception of the portion referring to a proposed amendment to the Constitution, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws and with the further exception of that portion relating to the resolution from Louisiana dealing with the Harrison Narcotic Act, which was referred to the Reference Committee on Legislation and Public Relations.

Report of Board of Trustees

Dr. Arthur W. Booth, Chairman, presented the report of the Board of Trustees as presented in the Handbook as well as the following reports, which were referred to the Reference Committee on Reports of Board of Trustees and Secretary:

MEMORIAL TO DR. CHARLES BENJAMIN WRIGHT

The Board of Trustees records with deepest sorrow the passing of one of its members, Charles Benjamin Wright, on May 31. Charles B. Wright ever since his graduation from the Johns Hopkins Medical School has been an important factor in American medicine, first as a teacher and then as a practitioner. In recent years he has played an important role in the American Medical Association and for seven years has been a member of the Board of Trustees. So valuable have been his services that several years ago he was elected Chairman of the Executive Committee of the Board. This office he held at the time of his death. The medical profession is under many obligations to Dr. Wright for his indefatigable labors in its behalf. Charles B. Wright was cut off in his prime. That genial and lovable character will long linger in the memory of his fellow men and in the hearts of the medical profession. Our love and deepest sympathy go to Mrs. Wright and her children in their irreparable loss.

INDICTMENT OF THE ASSOCIATION

The Supreme Court of the United States has denied the petition of the Association for a writ of certiorari; hence the Association must now stand trial in the U. S. District Court for the District of Columbia. Word has just been received to the effect that representatives of the Association and the members of the administrative personnel who were indicted by an additional grand jury impaneled at the request of the Department of Justice of the United States must be in Washington on Friday morning, June 14, to make an appearance before the court. The Board of Trustees has authorized the Secretary and General Manager to enter a plea of not guilty for the Association.

CHANGE IN NAME AND IN POLICIES OF COUNCIL ON FOODS

When the Council on Foods was first established in 1929 there was a need for a body of experts to express authoritative opinions about health claims for foods. The formation of a committee to evaluate foods and the claims made for them represented a logical development of the recognition—by physicians, the general public and members of the food industry—of the expansion of nutritional knowledge by scientific and clinical investigators. The work of the Council, under the auspices of the American Medical Association, has developed rapidly but now there seems to be good reason for the Council to relinquish certain of its activities and to expand other phases of its work.

Following the passage of the new Federal Food, Drug and Cosmetic Act, standards and definitions of foods are being drawn up and ingredients of packaged foods must be declared on labels. This step is gradually eliminating one feature of the Council's activities, namely, making known the composition of processed and packaged foods. Again, the Federal Trade Commission with the great powers conferred on it by the Wheeler-Lea Amendment is empowered to police objectionable claims in the advertising of food products. Thus the Council is largely relieved of the necessity of indicating by means of its seal of acceptance those claims which are considered unobjectionable.

There remains for the Council the highly important function of expressing authoritative group opinion on foods and the nutritional claims made for them. At the present time there exists no organization in the United States which is capable of serving this purpose. While the Council plans no longer to accept many common foods for which standards of identity and composition have been established, it is still considered desirable that the Council should study and report on such products when it is considered to be in the interests of the public to do so. Further, the Council deems it necessary to retain its present policy of giving consideration to products intended for the feeding of infants or the sick and to foods which have been manipulated by the addition of vitamins, minerals or other dietary essentials with the aim of improving their nutritional value. It is proposed further that more attention be devoted to the preparation of reports on the nutritive aspects of foods and combination of foods.

Under the circumstances the Board has authorized a change in the policies of the Council and in its name so that it be called the Council on Foods and Nutrition in order to emphasize the change in the direction of its work.

RESOLUTIONS AUTHORIZING ORGANIZATION OF A COMMITTEE ON MEDICAL PREPAREDNESS

The Chairman of the Board requested the Secretary to read the following Resolutions Authorizing the Organization of a Committee on Medical Preparedness, which were referred to the Reference Committee on Executive Session:

WHEREAS, The ravages of war again pervade many of the nations and peoples of the world; and

WHEREAS, The President of the United States has indicated to the nation and to the Congress the desirability of military preparedness so that our people may successfully resist attempts to substitute other forms of government for the democracy established by the Constitution of our country; and

WHEREAS, Organization of the nation for preparedness involves from the first the complete cooperation of the physicians of the country for:

1. Medical services in the Military, Naval, Aviation and Veteran's administrations;
2. Selection of men physically fit to serve with such agencies; and
3. Rehabilitation of those not physically qualified [to enable them] to participate in military activities; and

WHEREAS, Preparedness demands also

1. Medical service to the industrial workers engaged in war industries;
2. Continuance of medical care of the civilian population;
3. Education of young men to qualify them for medical service; and

WHEREAS, The American Medical Association now embraces in its membership more than 117,000 of the licensed physicians of the United States; and

WHEREAS, The headquarters of the American Medical Association have available facilities as follows:

1. Complete records of all qualified physicians in this country, with data necessary to determine largely their availability for military or other services;
2. Complete information concerning facilities for education in medicine, the medical specialties and other medical activities;
3. Complete information concerning the hospitals of the United States;
4. The necessary facilities for making prompt contact through addressing devices, periodicals and constituent bodies with all medical personnel and medical agencies; and

WHEREAS, Only in the headquarters of the American Medical Association, as far as is known, are such information and facilities available; and

WHEREAS, The American Medical Association is not only the largest but also the only organization containing in its membership qualified physicians in every field of medical practice; and

WHEREAS, During the World War of 1914-1918 the American Medical Association aided in making available the services of more than 60,000 physicians for military and related activities; therefore, be it

Resolved, That the House of Delegates authorize the Board of Trustees to create a Committee on Medical Preparedness, to consist of seven members of this House, with the President of the Association, the Secretary of the Association, the Secretary of the Board of Trustees and the Editor as ex officio members; and be it further

Resolved, That this Committee establish and maintain contact and suitable relationship with all governmental agencies concerned with the prevention of disease and the care of the sick, in both civil and military aspects, so as to make available at the earliest possible moment every facility that the American Medical Association can offer for the health and safety of the American people and the maintenance of American democracy.

Report of Judicial Council

Dr. George Edward Follansbee, Chairman, presented the report of the Judicial Council, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws.

Report of Reference Committee on Credentials

Dr. J. Newton Hunsberger, Chairman, stated that the reference committee had received credentials from Dr. W. Albert Cook and Dr. Walter A. Howard for one seat in the House of Delegates and that the committee had seated Dr. Cook. After discussion it was moved by Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Olin H. Weaver, Georgia, and carried, that the action of the reference committee in seating Dr. Cook be sustained.

Report of Council on Medical Education and Hospitals

Dr. J. H. Musser, Acting Chairman of the Council, presented the Report of the Council on Medical Education and Hospitals as presented in the Handbook, together with the following

supplementary report dealing with graduate medical schools, which was referred to the Reference Committee on Medical Education:

PRINCIPLES REGARDING GRADUATE MEDICAL SCHOOLS

The following principles, adopted by the House of Delegates in June 1923, have been revised and are submitted to the Council for its consideration.

1. *Organization*.—A graduate medical school should be incorporated as a nonprofit institution. Its board of trustees should be composed of public spirited men or women having no financial interest in the operations of the school or its associated hospitals. The trustees should serve for fairly long and overlapping terms. If the choice of trustees is vested in any other body than the board itself, that should be clearly stated. Officers and faculty of the school should be appointed by the board.

2. *Admission Requirements*.—(a) A physician who does not intend to limit his practice to a specialty shall present satisfactory evidence that he is a graduate of a medical school and that he is licensed to practice in the state in which he resides. (b) The physician who desires to prepare himself to specialize, or who has limited his practice to a specialty, shall present satisfactory evidence that he is a graduate of a medical school approved by the Council on Medical Education and Hospitals and that he has completed at least a one year internship in a hospital approved by the Council, or the equivalent.

3. *Records*.—The graduate school shall maintain (a) a full and accurate record of each student's qualifications, medical degree and licensure, (b) internship or equivalent training, (c) residency or equivalent training, (d) attendance in school, (e) proficiency as appraised by (1) medical contributions, (2) research, (3) membership in county medical society or other scientific bodies, (4) examination, (5) qualifying opinion by student's teachers. In the case of study for specialty, full record of the prescribed course and duration of study with attendance and final estimate of proficiency.

4. *Supervision*.—There should be careful and intelligent supervision of the school by a dean or other executive officer who holds and has sufficient authority to carry out the ideals of present day graduate medical education.

5. *Curriculum and Grading of Instruction Offered*.—The graduate school should have its various courses designed to prepare the physician for the practice of a specialty so graded that the student, if he desires, may follow a progressive and systematic program of two or more years' duration. If at some previous time, or in other institutions, the student has satisfactorily completed certain portions of the work, he may be given credit for the same, with a proportional advanced standing. Institutions offering courses leading to restricted practice in a specialty should provide (a) courses in anatomy, pathology, chemistry and the other basic preclinical sciences which apply to the respective specialties, (b) clinics in which students personally examine patients in hospital wards and out-patient departments and follow these patients throughout their illness, (c) courses of operative and laboratory—cadaver—technic appropriate to each specialty, and (d) for those especially qualified opportunity for research work with proper critical supervisions should be provided.

Short operative courses offered in any of the clinical specialties should include a full review with diagnostic and clinical courses so arranged that they become integral parts of a complete program.

6. *Teachers*.—The graduate medical school should have a faculty well trained in and responsible for instruction in all subjects in which courses for study are announced. Facilities should be provided for essential review and advanced work in the preclinical sciences. The faculty should be organized under competent department heads.

7. *Laboratories*.—The school should possess well equipped laboratories and clinical facilities. The postmortem rate shall be in conformity to the rules for approved hospitals.

8. *Library and Museum Facilities*.—The graduate school should have a medical library under the supervision of a com-

petent librarian and staff. It should include text and reference books, and bound medical periodicals and the essential indexes. For any library, the QUARTERLY CUMULATIVE INDEX MEDICUS is essential. It should receive regularly the more important medical periodicals, the latest numbers of which are easily accessible. The school should maintain adequate museum facilities, especially in anatomy and pathology.

9. *Hospitals and Dispensaries.*—The graduate medical school should have control of a teaching hospital with adequate outpatient clinic. It should have sufficient material to enable it to provide satisfactory clinical study in the fields of medicine in which courses are offered, so that students may personally examine patients in the hospital wards and in the dispensary and make the essential laboratory examinations.

10. *Annual Announcements.*—The graduate school should publish an annual announcement and bulletins or catalogues giving detailed information in regard to its courses of instruction, with teachers and details of the laboratories, dispensaries and hospital patients. It should outline the various opportunities for study offered in both fundamental and clinical branches and list those to whom advanced degrees or certificates were granted.

11. *Advanced Degrees and Certificates.*—No advanced degree or certificate should be granted to any one who has not demonstrated by examination or otherwise proficiency in his specialty, nor to any one who has not completed at least one academic year in full time study in the institution granting the certificate.

12. *Financial Support.*—Experience has shown that it is not possible to maintain high educational standards on income from student fees alone. Other sources of financial support are deemed essential for the proper conduct of graduate medical schools and should be listed in the annual announcement.

Report of Council on Scientific Assembly

Dr. James E. Paullin, Chairman, presented the report of the Council on Scientific Assembly, which was referred to the Reference Committee on Sections and Section Work.

Report of Committee to Confer with Governmental Agencies

The Secretary stated that Dr. Irvin Abell, Chairman of the Committee to Confer with Governmental Agencies, had left his report in the hands of the Secretary because he could not be in attendance until Tuesday.

It was suggested that the report be deferred until the Executive Session, and without objection the report was passed until a later meeting of the House.

NEW BUSINESS

Resolutions Susceptible of Misrepresentation to Be Considered in Executive Session

Dr. Walter E. Vest, West Virginia, presented the following resolution, which was adopted on motion of Dr. Vest, seconded by Dr. E. G. Wood, Tennessee, and carried:

WHEREAS, Many problems of a nature critical to the life and work of the American Medical Association now concern us; and

WHEREAS, Such problems as are concerned with public relations efforts, legal difficulties, contraception and the relations of the organized medical profession to the federal administration are susceptible of misrepresentation and misunderstanding in the reflection to the public; therefore be it

Resolved, That all matters of such character be referred by the Speaker of this House of Delegates for consideration in executive session, and that, in conformance with the purpose of this resolution, each delegate who offers a resolution be requested at the outset to state the subject thereof and that the Speaker then rule, before such resolution shall be read, whether or not it be considered in executive session.

Resolutions on Conservation of Eyesight

Dr. James R. McVay, Missouri, presented the following resolutions in behalf of the Missouri State Medical Association, which were referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, The term "conservation of eyesight" carries broader implications than the term "prevention of blindness"; and

WHEREAS, There is need of extending the educational program in the conservation of eyesight throughout the country; and

WHEREAS, The various constituent state medical associations of the American Medical Association should be encouraged to establish committees on the conservation of eyesight; therefore be it

Resolved, That this House of Delegates support and encourage the constituent state medical associations to establish such committees, and that the Board of Trustees of the American Medical Association be requested to appoint a committee to direct this educational program or to instruct the Bureau of Health Education to assume this responsibility based on the facts found and reported by the special committee which was appointed by the Board of Trustees in accordance with the request of the House of Delegates at the 1939 session, for the purpose of studying all phases of the problem of prevention of blindness; and be it further

Resolved, That our delegates be instructed to present this resolution to the House of Delegates of the American Medical Association at the New York session in June 1940.

Proposed Amendment to By-Laws

Dr. James E. Paullin, Section on Practice of Medicine, presented the following amendment to chapter VIII, section 1, of the By-Laws, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws:

Amend section 1, chapter VIII, of the By-Laws to read as follows:

SECTION 1. MEMBERSHIP.—The Standing Committees, or Councils, including the Judicial Council and the Council on Scientific Assembly, shall consist of five members, each elected for five year terms. The Council on Medical Education and Hospitals shall consist of seven members, each elected for seven years. The terms of office of the members of each council shall terminate in succession, one each year, and, except in the case of the Council on Medical Education and Hospitals, the House of Delegates shall, on the nomination of the President, elect one member each year to fill the vacancy. With respect to the Council on Medical Education and Hospitals, one member shall be elected annually by the House of Delegates on the nomination of the Board of Trustees. The members of the Council on Scientific Assembly shall be chosen, as far as practical, from ex-section officers representing different sections. The President-Elect, the Secretary of the Association and the Editor of THE JOURNAL shall be ex officio members of the Council on Scientific Assembly.

Procurement of Professional Personnel for Medical Corps of Army in Event of a National Emergency

Dr. George C. Dunham, United States Army, presented the following plan for the procurement of professional personnel for the Medical Corps of the Army in the event of a national emergency, which was referred to the Reference Committee on Executive Session:

The following is a tentative plan for the procurement of professional personnel for the Medical Corps of the Army in the event of a national emergency. This plan has been prepared by the office of the Surgeon General of the Army and is submitted to the House of Delegates of the American Medical Association for its consideration.

1. The American Medical Association to be asked to conduct a survey of the medical profession through its state and local activities.

2. The local or county societies to canvass their members to determine of those who express a willingness to serve who should be available for the military service and who, on account of their age, physical disability or commitment in civil capacities, should remain at home.

3. The county society to give to each one who expresses his willingness to serve, even though he may be selected to remain at home, a button similar to that which was designed for the Volunteer Medical Service Corps during the last war.

4. The county societies to list those who are selected for the military service according to their professional qualifications, listing as surgeons, psychiatrists and so on only those who are members in the national specialists' organizations. Also to select from those who are to remain at home qualified men for examining boards.

5. The state societies to maintain an available roster of their members.

6. The American Medical Association to maintain a numerical roster of availability by states.

7. The Medical Department of the Army to have one or more selected officers on duty at the headquarters of the American Medical Association in Chicago.

8. The War Department, Corps Areas or regional officers to call on the American Medical Association for physicians or specialists, as and when required.

9. The American Medical Association to call on the states, according to their quotas, for the physicians required.

10. The states, in turn, to call on their local societies for their quota of physicians.

In the quotas, credits would be given for sponsored units and preference would be given to reserve officers wherever their qualifications warrant.

It appears that in the event of a national emergency of great magnitude it would be very necessary to conserve the medical profession. This plan would distribute the professional load and, if properly administered, should prevent the stripping of rural and isolated communities of their necessary medical personnel.

There could be an extension of this plan to cover the training program for technicians. The same societies could conduct a survey of the teaching institutions to determine their availability and suitability for the training of such enlisted specialists as would be required. Rational medical service for civilian groups in war industries could be coordinated by the same administrative units.

Resolutions on Venereal Disease Program

Dr. J. N. Baker, Alabama, presented the following resolutions, which were referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, An expanded program for the control of the venereal diseases throughout the states has been made possible by federal grants-in-aid to states to be used specifically for this purpose; and

WHEREAS, On state health departments has been placed the responsibility for the judicious and wise expenditure of such funds; and

WHEREAS, The organized medical profession of this country has likewise a responsibility in this particular problem, as it has in all other health problems affecting the nation; and

WHEREAS, Because of the magnitude and scope of any nationwide program looking to the control of the venereal diseases, the House of Delegates of the American Medical Association recognizes the need for the fullest cooperation, aid and counsel from the practicing profession; and

WHEREAS, The proper control of these diseases depends on adequate, continued treatment; and

WHEREAS, The treatment of the sick individual is the province of the practicing physician; and

WHEREAS, The modern techniques employed in the treatment of the venereal diseases require a familiarity with such techniques as well as a knowledge of the diseases themselves; therefore be it

Resolved, That it is the sense of this House of Delegates that such cooperation on the part of the medical profession should be freely extended and that the official health agencies, state and local, charged with the administrative responsibilities for the conduct of the program be urged to formulate plans and machinery for as full utilization as possible of such members of the local medical profession as are willing and competent to undertake the clinical management of such programs; and be it further

Resolved, That it is the sense of this House of Delegates that constituent state medical associations and component county medical societies should cooperate fully in the effort to improve the quality of clinical services to be rendered in venereal disease control programs; and be it further

Resolved, That it is the sense of this House of Delegates that a reasonable compensation should be paid physicians serving in the venereal disease clinics; and be it further

Resolved, That it is the sense of this House of Delegates that, because of the potential dangers of intravenous therapy, such medication should be administered only by a duly qualified physician.

Resolution on Military Service by Women Physicians

Dr. Samuel J. Kopetzky, New York, presented the following resolution from the American Medical Women's Association, Inc., as well as a similar resolution from the Women's Medical Association of New York City, which was referred to the Reference Committee on Miscellaneous Business:

The American Medical Women's Association, Inc., now in session at the Park Lane Hotel, respectfully requests the House of Delegates of the American Medical Association actively to consider the question of providing for its women physician members in the event of war and to approach the War Department, or proper authorities, in order to secure proper military recognition and commissions for women physicians and surgeons, so that in giving their all to their country they may be assured of the same rating and benefits of government protection that their brother colleagues enjoy.

Resolution on Legislation Having to Do with the Care of the Sick

Dr. John Z. Brown, Utah, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

Resolved, That the Utah State Medical Association, having heard of the recent vote of the House of Delegates of the American Medical Association on the subject of state medicine, extends a vote of support to the officers and delegates of that Association on the principle involved; and be it further

Resolved, That it is the sense of the Utah State Medical Association that it is not incompatible with the principles of the American Medical Association to have that organization formulate and propose to the appropriate government agencies some plan whereby the proper governmental agency will compensate adequately the family physician for the care and treatment of patients in the low income brackets who are unable to pay for medical and hospital services; and be it further

Resolved, That nothing in this resolution shall be construed as suggesting or recommending any plan whereby the free choice of physician or hospital by the patient shall be jeopardized; and be it further

Resolved, That it is the sense of this Association that any plan adopted should be administered by a doctor of medicine who is trained in the diagnosis and treatment of disease and not under the supervision of a public health officer, whose special training is directed toward the prevention rather than the treatment of disease; and be it further

Resolved, That the Utah delegate to the 1940 session of the American Medical Association exert every effort to have some plan prepared and presented to the appropriate governmental agencies with a view to carrying out the intents and purpose of this resolution.

Resolution on Doctor's Day

Dr. Harvey F. Garrison, Mississippi, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, Senator Theodore G. Bilbo of the state of Mississippi introduced into the United States Senate the following resolution declaring June 22 a day to be known as "Doctor's Day," on which the public may officially recognize the services rendered by the medical profession to the people: "Resolved, etc., That the 22d day of June in each year is hereby designated, and shall hereafter be known as, Doctor's Day in commemoration of the great sacrifices and untiring efforts and devotion of the members of the medical profession in performing their duty to humanity by caring for the sick and injured in times of individual need and during periods of pestilence, war and other disasters and catastrophies. Sec. 2. The President is authorized and requested to issue annually a proclamation calling upon officials of the Government to display the United States flag on such day and inviting the people of the United States to observe such day in an appropriate manner," and

WHEREAS, This resolution was unanimously passed by the United States Senate; therefore be it

Resolved, That the House of Delegates of the American Medical Association express to the United States Senate and to Senator Bilbo its deep appreciation of this recognition.

Resolutions on Care of Needy Physicians

Dr. Charles A. Dukes, California, presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The care of physicians who are in need is a subject worthy of the attention of the constituted units of organized medicine; and

WHEREAS, A serious study and survey of this problem is definitely indicated; now be it

Resolved, By this House of Delegates of the American Medical Association that the speaker of the House of Delegates be instructed to appoint a committee of three to make a study of the problem of (1) Aid to needy members of this Association and (2) Establishment of a national fund for this purpose, and to submit a report of this study with recommendations at the next annual session of the House of Delegates; and be it further

Resolved, That the committee so appointed be empowered to appoint a subcommittee of three from members of each constituent state medical association to carry on similar studies in their respective states and to report thereon through the committee of the American Medical Association.

Resolution on Blood Typing for Blood Transfusion

Dr. T. K. Gruber, Michigan, in behalf of the Michigan State Medical Society, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The value of blood transfusion in the treatment of a wide variety of disabilities is firmly established; and

WHEREAS, The usefulness of this procedure in emergencies is totally dependent on the ready availability of suitable donors; therefore be it

Resolved, That the American Medical Association and its constituent state and component county organizations formulate a plan that may be linked with the present day project of blood testing for syphilis, for widespread blood typing and classification of the general public so that suitable donors shall be available at all times in every community throughout the United States.

Resolutions on Specialists in Hospitals

Dr. Thomas A. McGoldrick, New York, presented the following resolutions, which were referred to the Reference Committee on Medical Education:

These resolutions were approved by the Medical Society of the State of New York at its 1940 annual meeting. It was there ordered that they be presented to the American Medical Association at its 1940 annual session for consideration.

ORGANIZATION SECTION

JOUR. A.
JUNE 22,

Economics and the Committee on Medical Care to take appropriate toward the coordination of medical service plans and to arrange the collection of information and experience that may be useful developing and maintaining sound practices.

Address of Surgeon General James C. Magee

Dr. Arthur W. Booth, Chairman of the Board of Trustees presented Dr. James C. Magee, Surgeon General of the United States Army, who addressed the House as follows:

Mr. Chairman and Gentlemen:

I am not in any sense prepared to make a speech. I had not expected to stand here at all. On this sudden and pressing invitation, I will have to impose on you for a moment. I realize the significance and great importance of this meeting, particularly in reference to the thought that pervades the minds of all of us with reference to the disturbed state of world affairs.

Representatives of my office have already made some proposals, I understand, to the House of Delegates. As Surgeon General of the Army, I know that in the event of actual mobilization and the necessity for military effort on the part of our country, this is the organization on which we must rely for support when the occasion demands. This is my first appearance before the House of Delegates. I am exceedingly glad to be here and I hope to be on close terms with a great many of you as time goes on.

Report of Board of Trustees

Dr. Arthur W. Booth, Chairman of the Board of Trustees, read the following Report of the Bureau of Medical Economics on fee schedules, which was referred to the Reference Committee on Miscellaneous Business:

The Bureau of Medical Economics has studied the fee schedules reported by county medical societies and submits the following report, as requested by the House of Delegates at the San Francisco session in 1938: Special purposes often require the adoption of fee schedules in connection with the administration of medical care. Under such circumstances fee schedules do not violate the Principles of Medical Ethics.

When it becomes necessary to adopt fee schedules, the purpose for which such schedules are designed, the body which is to pay for the services, the ability of patients to pay, the length of time over which the schedules are to remain effective, the economic conditions in the area involved and the nature of the medical services to be provided must be considered in arriving at the values to be ascribed to the schedule items.

Ordinarily, fee schedules should provide for sufficient elasticity to permit their adaption to wage levels, specialized services and variations in the costs of providing medical care in urban and rural districts.

The adoption of fee schedules is the function of component units, with the advice and assistance, if desired, of the state medical societies of which they are a part.

Resolution on Military Status of and Pay to Physical Therapy Technicians

Dr. Rollo K. Packard, Illinois, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

Resolved, That the American Medical Association express its approval of Senate Bill 1615, introduced by Senator Sheppard, chairman of the Senate Military Affairs Committee, and House Bill 8542, introduced by Mr. May, chairman of the House Military Affairs Committee. These bills give the same military status and pay to the physical therapy technicians who are now in the Army or who will come into the Army during an emergency as the Army nurses now have.

Resolution Concerning Certain Objectionable Practices of Insurance Companies

Dr. John H. Fitzgibbon, Oregon, presented a resolution concerning certain objectionable practices of insurance companies, which was referred without reading to the Reference Committee on Executive Session.

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by various delegates and carried, the House recessed at 2:10 p. m., to reconvene at 9:30 a. m. Tuesday, June 11.

(To be continued)

Resolved, That in order better to serve the hospitals with which they are connected and to improve that service by greater cooperation and understanding, the Joint Council of Pathologists, Radiologists, Anesthesiologists and Physical Therapy Physicians of New York state recommends that all grade A hospitals shall have physicians especially trained in pathology, radiology, anesthesiology and physical medicine in charge of these departments, and that the directors of these departments shall be members of their respective medical boards with the power to vote; and be it

Resolved, That in those areas in which the foregoing specialties are not represented by specialists it shall be permissible for physicians trained in these specialties to represent the specialty on their respective medical boards.

Resolutions on Limiting Type and Extent of Services Offered by Laboratories of State Boards of Health

Dr. L. W. Larson, Section on Pathology and Physiology, presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The continued growth and development of that special branch of medicine known as clinical pathology is necessary for the proper diagnosis and treatment of the sick and is essential to the science and practice of medicine; and

WHEREAS, The growth of laboratories of state boards of health has been abnormally augmented by grants-in-aid from the federal government, the effect of which is to extend these services to all citizens without regard to their ability to pay; and

WHEREAS, The excessive development of laboratory medicine by state boards of health serves as an entering wedge for state medical practice which apparently will include all medical specialties; and

WHEREAS, These practices will inevitably result in the curtailment of the practice of clinical pathology and tend to discourage young, well trained physicians from entering this essential field; be it therefore *Resolved*, That the House of Delegates recommend to all state medical boards of health with the view of limiting the type and extent of services offered by the laboratories of these organizations. Laboratory services by the state board of health laboratories should be confined to requests made by health officers and to those made by physicians whose patients find it difficult or impossible to pay the cost of laboratory services of this kind in the customary manner. In general, laboratories of the state boards of health should not provide services at taxpayers' expense to persons who are able to provide for themselves; and be it further *Resolved*, That the House of Delegates authorize the Board of Trustees of the American Medical Association to undertake an educational campaign to set forth this problem to the medical profession.

Resolution on Approval of the American Foundation for Tropical Medicine, Inc.

Dr. Peter Irving, New York, presented the following resolution, which was referred to the Reference Committee on Medical Education:

WHEREAS, Tropical medicine has attracted increasing attention in the United States; and

WHEREAS, in 1934 there was created an organization known as the American Academy of Tropical Medicine; and

WHEREAS, Following that event there was organized the American Foundation for Tropical Medicine, Inc., which has elaborated a plan for the introduction of graduate students in tropical medicine from South and Central America to study in the Graduate School of Tropical Medicine at the Tulane University of Louisiana and other appropriate universities in the United States for the improvement of health in the Western Hemisphere and the interchange of cultural assets; and

WHEREAS, The American College of Physicians has voted its approval of this foundation; therefore be it

Resolved, That the American Medical Association register its formal approval of the American Foundation for Tropical Medicine, Inc.

Resolution on Military Activities

Dr. George R. Dillinger, Indiana, presented a resolution on Military Activities, which was referred without reading to the Reference Committee on Executive Session.

Resolution on Medical Service Plans

Dr. L. G. Christian, Michigan, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, Medical societies in more than eighteen states have medical service plans in operation or in an advanced stage of development; and

WHEREAS, It is of the utmost importance that organized medicine maintain a close and sympathetic interest in the administration and policies of medical service plans; and

WHEREAS, There is need for uniformity in the standards of such plans and in the methods of collecting actuarial data; and

WHEREAS, There are indications, if medical service plans do not have the benefit of coordinated leadership, that agencies other than medical may assume the direction of such plans; therefore be it

Resolved, That the House of Delegates of the American Medical Association request the Board of Trustees to direct the Bureau of Medical

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—H. R. 9209, the Military Establishment Appropriation Bill for the fiscal year of 1941, as passed by the House and Senate, carries an appropriation of \$130,000 for the preparation of plans for a new building in which to house the Surgeon General's Library. On June 10, when the conference report on the bill was before the House, Representative Collins, Mississippi, sought to amend the bill so as to make available an additional sum of \$470,000 for the acquisition of a site for the building. This amendment was rejected on a point of order. A subcommittee of the Senate Committee on Education and Labor recently concluded hearings on S. 3461, a bill introduced by Senator Murray, Montana, proposing to provide for the general welfare by enabling the several states to make more adequate provisions for the control and prevention of industrial conditions hazardous to the health of employees. The bill designates the Department of Labor as the administrative agency. On June 13 the committee discussed the bill but took no action with respect to it. H. J. Res. 551 has been signed by the President, making effective as of June 30 Reorganization Plan No. IV, transferring to the Federal Security Agency the Food and Drug Administration, except those functions relating to the administration of the Insecticide Act of 1910 and the Naval Stores Act, which will remain in the Department of Agriculture.

DISTRICT OF COLUMBIA

Changes in Status.—S. 2013 has passed the Senate and House, proposing to amend the Code of the District of Columbia to provide for the organization and regulation of cooperative associations. S. 3720 has been reported to the Senate, with amendments, creating a Board of Funeral Directors and Embalmers. H. R. 7865 has been reported to the Senate, proposing to amend the laws regulating the practice of dentistry.

H. R. 8692 has been reported to the Senate, proposing to amend existing laws regulating the practice of podiatry in the District of Columbia.

STATE MEDICAL LEGISLATION

Louisiana

Bills Introduced.—H. 934 proposes to prohibit the retail sale or distribution, except on the written order of a physician, dentist or veterinarian, of amytal, luminal, veronal, barbital, acid diethylbarbituric, paraminobenzene sulfonamide, sulfanilamide, sulfamide, prontosil, neo-prontosil, neo-prontylin, sulfamethylthiazole, dinitrophenol, edimalin, sulfonamid, cincophen, thyroid, aminopyrine or any of their salts or derivatives, or compounds of the foregoing substances, or any preparation or compound containing any of the foregoing substances, or their salts, derivatives or compounds, or any registered, trade-marked or copyrighted preparation or compound registered in the United States patent office containing more than 1 grain to the avoirdupois or fluid ounce of the above substances. H. 508 proposes to require every physician who attends a woman for conditions relating to pregnancy to offer to take or have taken a sample of her blood at the time of first examination, if no objection is made thereto by the woman, and to submit such sample to an approved laboratory for a standard test for syphilis. The bill proposes that a standard test for syphilis be a test approved by the American Board of Pathology and must be made by a laboratory operated by a licensed physician and pathologist as recognized by the American Board of Pathology. All persons other than physicians permitted by law to attend pregnant women but not permitted to take blood samples are to be required to cause a sample of blood of the woman to be taken by a licensed physician, if no objection is made thereto by such woman, and submitted to an approved laboratory for a standard test for syphilis.

WOMAN'S AUXILIARY

Michigan

A joint meeting of the Gratiot-Isabella-Claire County Medical Society and its auxiliary was held in Alma recently with ninety persons in attendance. Mr. William J. Burns, executive secretary of the Michigan State Medical Society, spoke on "Opportunities for the Doctor's Wife."

Dr. Nathan Sinai, of the University of Michigan, spoke on "Highways and Horizons of Medicine in This Changing World" at a recent meeting of the auxiliary to the Wayne County Medical Society in Detroit. Drs. J. Milton Robb and Edward D. Spalding spoke on the Wagner Health Bill at the December meeting.

Minnesota

More than 10,000 papers on the subject "Youth's Health Security" were written by Minnesota High School students in the Christmas Seal High School Radio project which is conducted under the auspices of the Minnesota Public Health Association and the Woman's Auxiliary of the Minnesota State Medical Association. A total of 102 talks, selected from the 10,000, were submitted in the state contest. Writers of six papers, selected from the 102 entries, presented them over radio station WCCO.

The auxiliary to the Clay-Becker Counties Medical Society sponsored a sale of articles made by the patients at Sand Beach Sanatorium recently. The sum of \$78.85 was made for the patients. The auxiliary has placed *Hygeia* in all public libraries of the county. Dr. W. L. Burnap spoke on the Wagner Bill at the joint meeting of the Red River Valley Medical Society and the woman's auxiliary in Crookston recently.

New Jersey

The auxiliary to the Atlantic County Medical Society met in Atlantic City January 12. Dr. Harold Davidson spoke on cancer. At an open meeting at the Woman's Club, January 16, Dr. Harold Davidson spoke on cancer and Mrs. A. Haines Lippincott, of Camden, spoke on the Woman's Field Army of the American Society for the Control of Cancer.

The auxiliary to the Camden County Medical Society met in Woodbury January 16. Miss Jane C. MacNeal, director of social service of the Pennsylvania Hospital, Philadelphia, and Rev. Robert D. Morris, supervisor of the theological service of the Pennsylvania Hospital, spoke on "Medical Social Work."

The auxiliary to the Union County Medical Society met in Rahway January 16. Dr. Elizabeth Ford Love spoke on child behavior problems.

The board of directors of the auxiliary to the Medical Society of New Jersey met in Trenton January 8. Dr. Hammel Shipps reviewed recent progress in medicine and Dr. Thomas K. Lewis discussed state medicine.

New York

The auxiliary to the Cayuga County Medical Society met in Auburn January 18. Dr. George B. Adams discussed public health work in the county.

The auxiliary to the Kings County Medical Society held its January meeting in Brooklyn. Dr. George Merrill spoke on "Allergy"; an article from *Hygeia* was reviewed and plans were made for securing funds for the Physicians' Home.

Dr. Raymond Graham spoke on "The History of Medicine in Onondaga County" at a recent meeting of the auxiliary to the county medical society in Syracuse.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

DISTRICT OF COLUMBIA

Mr. Cummings Endows Research on Heart Disease.—Homer S. Cummings, LL.D., formerly attorney general of the United States, has given \$1,200 for five years to George Washington University, beginning in July, to establish a research clinic for the treatment of heart disease. The gift is to be known as the Cecilia Cummings Research Fund in honor of Mr. Cummings' wife who died from a heart disease in August 1939. It will be under the supervision of Dr. Paul F. Dickens, clinical professor of medicine, George Washington University School of Medicine, Washington.

IDAHO

Society News.—A recent meeting of the North Idaho District Medical Society at Lewiston was addressed by Drs. Richard J. Bailey and William N. Myhre, Spokane, Wash., on "Recent Advances in Treatment of Common Skin Diseases" and "Treatment of Heart Disease" respectively. The annual spring meeting of the Southwestern Idaho District Medical Society in Boise, April 17-18, was addressed by Drs. Howard C. Stearns on endometriosis; Joyle Dahl, treatment of syphilis, and Morris L. Bridgeman, pediatrics. Clinics on pediatrics, dermatology, obstetrics and gynecology formed a part of the session. The speakers are members of the faculty of the University of Oregon Medical School, Portland. The program was under the auspices of the state division of public health.

ILLINOIS

County Society Celebrates Anniversary.—The Pike-Calhoun County Medical Society celebrated the fortieth anniversary of its founding at a meeting in Pittsfield, April 19. Dr. James H. Hutton, Chicago, spoke on "The People, the Physicians and the Politicians" and Dr. Harold M. Camp, Monmouth, "Medicine Accepts the Challenge." A symposium on the treatment of peptic ulcer was presented by Drs. Thomas D. Masters, Robert J. Patton and Charles L. Patton, Springfield.

Chicago

The New Wesley Hospital.—Ceremonies marking the laying of the cornerstone of the new Wesley Memorial Hospital were held May 26. Franklyn Bliss Snyder, LL.D., president of Northwestern University, and Dr. Raymond W. McNealy, chief of staff of the hospital, were among the speakers. The hospital is planned as the first unit in a group of buildings to be known as the George Herbert Jones Hospital Center. Mr. Jones, founder and former president of the Inland Steel Company, in 1937 gave about \$2,000,000 in stock to finance the new hospital. In February of this year he gave additional shares of stock valued at more than \$1,000,000. The site is at Fairbanks Court and Superior Street, adjacent to the campus of Northwestern University. The building will be twenty stories high with a capacity of 525 beds. While it will have facilities for charity patients, the accommodations are designed for persons of moderate means. The new Wesley Memorial Hospital is affiliated with Northwestern University Medical School.

KANSAS

Personal.—Dr. Ralph M. Fellows has announced his resignation as superintendent of the state hospital at Osawatimie, effective May 30. He has accepted a position in the Milwaukee County Hospital for Mental Diseases, Wauwatosa, the state journal reported. Drs. Mirl C. Ruble, Parsons, and Henry E. Haskins, Kingman, have been reappointed to the Kansas State Board of Medical Registration and Examination.

Society News.—Dr. George F. Gesell, Wichita, recently discussed "Evaluation of Ocular Discomfort" before the Cowley County Medical Society in Winfield. The Montgomery County Medical Society was addressed in Coffeyville, April 19, by Dr. Wilson A. Myers, Kansas City, Mo., on "Heredity Transmission of Familial Diseases." The Wyandotte County Medical Society was addressed in Kansas City, May 21, by Drs. Harry W. King on "Acute Cholecystitis and Anomalies of the Bile Passages" and John H. Luke, "Chemotherapy."

Dr. Logan Clendening, Kansas City, Mo., discussed "Medical Literature and the Modern Practice of Medicine" before the society, May 7. The society was addressed, April 16, by Drs. Clarence A. Gripkey, Kansas City, on "Treatment of Thyroiditis"; Lewis G. Allen, Kansas City, "When Is a Colles' Fracture Reduced"; Mahlon H. Delp, Kansas City, Mo., "Treatment of Coronary Occlusion," and Oscar W. Davidson, Kansas City, "Urologic Treatment of Hypertension."—A symposium on carcinoma of the stomach was presented before the Shawnee County Medical Society in Topeka, May 6, by Drs. Floyd C. Taggart, Arthur K. Owen and William M. Mills.

MASSACHUSETTS

State Medical Election.—Dr. Walter G. Phippen, Salem, was reelected president of the Massachusetts Medical Society at its recent annual meeting in Boston. Dr. Alexander S. Begg and Charles S. Butler, Boston, were reelected secretary and treasurer, respectively. Dr. Frank R. Ober, Boston, was elected vice president.

Charity to Correct Speech Defects.—The Institute for Speech Correction, Inc., has recently been organized to give instruction in overcoming stammering, lisping and other speech defects exactly at cost. It has taken over the Boston Stammerers' Institute, which according to the *New England Journal of Medicine* was the oldest school of its kind in America, having been founded in 1867. Arrangements have been made with Emerson College whereby adequately supervised advanced students in speech pathology will instruct without charge any pupil at the institution who, on recommendation of his family physician, cannot pay for his lessons. Samuel D. Robbins, permanent secretary of the American Speech Correction Association and professor of psychology at Emerson College, has been elected managing trustee. He was for twenty-five years director of the Boston Stammerers' Institute.

New School of Dental Medicine at Harvard.—Harvard University will inaugurate in 1941 an entirely new five year course in dental education, it was announced June 16. The course, which will combine the basic knowledge and skills of both medicine and dentistry, is designed to train new types of scientific workers for the attack on dental disease. The new development has been made possible by the gift of \$650,000 from the Carnegie Corporation, \$400,000 from the Rockefeller Foundation and \$250,000 from the John and Mary R. Markle Foundation. A balance of \$250,000 bringing the total to \$1,550,000 is required to fulfil the program. The president and fellows of Harvard College have also transferred to the resources of the school of dental medicine \$1,000,000 tentatively placed at the disposal of the dental school ten years ago. The dental school will be renamed the Harvard School of Dental Medicine. Dental students will register in both the school of dental medicine and in the Harvard Medical School, taking three and one half years of the same medical courses as other students in the Harvard Medical School and in addition one and one half years of specific dental training. Graduates will receive both the M.D. and D.M.D. degrees. Admissions to the school of dental medicine will be governed by the same standards and the same committee which govern admissions to the Harvard Medical School. The last class to enter the present four year dental curriculum at Harvard will be admitted this coming September and the new program will go into operation in the fall of 1941. Harvard, the first university in America to establish a dental school, thus becomes the first university to institute this particular plan in the development of dental and medical education.

MICHIGAN

Annual Fracture Day.—The second annual fracture day, sponsored by the Flint regional fracture committee, was held at Hurley Hospital, Flint, May 15. The speakers were:

Dr. Hardie B. Elliott Jr., Head Injuries.
Dr. James A. Spencer, Management of Burns.
Dr. Myron W. Clift, Pathologic Fractures.
Dr. Leon M. Bogart, Emergency Treatment of Fractures.
Frederick C. Thorold, D.D.S., Fractures of the Jaw.
Dr. George J. Curry, Management of Long Bone Fractures.
Dr. Donald R. Brasie, Care of Traction Apparatus.
Dr. Harold W. Woughter, Carpal Bone Fractures.

MINNESOTA

Clarence M. Jackson Lecture.—Dr. Walter C. Alvarez, Rochester, delivered the seventh annual Clarence M. Jackson lecture, April 26, at the University of Minnesota. His subject was "Functional Gastro-Intestinal Disturbances." The lecture was sponsored by the Minnesota chapter of Phi Beta Pi Medical Fraternity.

Personal.—A special program was offered by the Luverne Rotary Club, April 1, to mark the fiftieth anniversary of Dr. Charles O. Wright in the practice of medicine.—Dr. Bernard H. Simons has been named health officer of Chaska.—Dr. Bernard A. Watson has resigned as head of the student health service at the University of Minnesota, Minneapolis, to join the staff of the Battle Creek Sanatorium, Battle Creek, Mich.

Abortionist Sentenced.—Mrs. Della Mostert, aged 60, was sentenced to a term of from two to eight years at hard labor in the Women's Reformatory at Shakopee, following her plea of guilty to an information charging her with the crime of abortion. The statutory penalty for criminal abortion is not to exceed four years, but the sentence in this case was doubled because of a previous conviction in 1936 for a similar offense. The recent investigation disclosed that Mrs. Mostert had performed an abortion on a 14 year old Negro girl, May 8.

NEW YORK

Society News.—Dr. Paul W. Beaven, Rochester, recently addressed the Chautauqua County Medical Society in Fredonia on "Abdominal Pains in Children."—Dr. George Douglas L. Taylor, Montreal, addressed the Franklin County Medical Society in April on "Arthritis and Rheumatism, Diagnosis and Treatment."—Drs. Samuel A. Thompson and Milton J. Raisdeck, New York, addressed the Schenectady County Medical Society in Schenectady recently on "Surgical Treatment of Coronary Artery Disease with Special Reference to Cardiopericardiopexy" and "Selection and Postoperative Management of Patients in the Surgical Treatment of Coronary Disease" respectively.—Dr. Harry L. Segal, Rochester, addressed the Wayne County Medical Society, Lyons, in April on "Management of Bleeding Ulcers."

Medal for Service to Community.—Dr. John R. Williams has been awarded the Albert David Kaiser Medal of the Rochester Academy of Science "for service to the community and to the medical profession." The citation stated that Dr. Williams "has been the leading spirit, guide and director in the establishment of the Medical Museum in the Rochester Academy of Medicine, which from its beginning has maintained a high standard of educational value for the medical profession and the public. This museum, a new department of academy activity, has already brought into active participation a large number of the medical profession who formerly had no opportunity to take part, as individuals, in the problems of education which face the medical profession." Dr. Williams graduated at the University of Michigan Medical School, Ann Arbor, in 1903.

Typhoid Carrier for Forty-Nine Years.—The New York State Department of Health reported, May 12, the case of a typhoid carrier, "Typhoid Sally," who, according to *Health Notes*, has been a carrier for forty-nine years. The condition of the woman, a cook, was discovered in 1925 when health officers investigated an outbreak of typhoid in a hotel where "Sally," aged 57, was working in the kitchen. Her case history disclosed that when she was 23 years of age she suffered a severe illness which was treated as malaria but which physicians later believed to be typhoid. A few years later the woman was found on a dairy farm when her husband complained to the health department of "a typhoid scare" and asked to have milk from his farm tested. "Sally" was cautioned against the handling of milk as well as of food. In 1928, health authorities investigated another case of typhoid and learned that "Sally" had been preparing food again. By 1939 eleven cases were traced to her and she subsequently was convicted of a violation of the state sanitary code and was fined \$25.

Dr. Corner Receives First Squibb Award.—Dr. George W. Corner, professor of anatomy and curator of the medical library, University of Rochester School of Medicine, was presented at a dinner June 10 with the first E. R. Squibb & Sons Award for his contributions to endocrinology. The award is the sum of \$1,000 and a scroll provided by the association. Dr. Corner was recently appointed director of the embryologic laboratory of the Carnegie Institution. He will begin his new work in Baltimore July 1. Speakers at the dinner when the prize was presented included Philip E. Smith, Ph.D., professor of anatomy, Columbia University College of Physicians and Surgeons, New York, and Dr. Elmer L. Sevringhaus, professor of medicine, University of Wisconsin Medical School, Madison, chairman of the committee which drew up the regulations for the award. Dr. Corner first worked out the relation of the corpus luteum to the sex cycle in detail in the mammal (sow). He later showed that corpus luteum extract in the ovariectomized rabbit could cause progestational (premenstrual) development of the uterus and maintain pregnancy. His early experiments with Dr. Willard M. Allen led to the isolation of pure corpus luteum

hormone (progesterone). In 1923 he showed by studies on the monkey that menstruation could occur without ovulation. He was the first to show that estrogens may delay the menstrual cycle.

New York City

Professors Appointed.—Dr. Wesley C. Bowers, director of the ear, nose and throat department of St. Luke's Hospital, has been named clinical professor of otolaryngology at Columbia University College of Physicians and Surgeons and Nicholas Kopeloff, Ph.D., research bacteriologist at the New York State Psychiatric Institute, has been appointed assistant professor of bacteriology. Dr. Bowers graduated from Columbia in 1908 and Dr. Kopeloff took his Ph.D. degree at Rutgers University in 1917.

Degree of Doctor of Public Health.—The degree of doctor of public health has been established at the DeLamar Institute of Public Health, Columbia University College of Physicians and Surgeons, to meet the demand for specialized training in the field. According to *Science*, the large expansion of public health activities and the increase in federal, state and local appropriations for such programs are creating many new positions which call for specialized education of a high order. The degree has been introduced at Columbia as part of the program of the institute to supply qualified physicians to fill these posts. Students who wish to matriculate for the degree must be graduates of an approved medical school and have served an internship of at least one year in a recognized hospital. The program of studies for the degree includes two years of graduate work, one of which must be spent at the institute. If the student chooses, permission may be granted to do one year of field work in some locality other than New York.

Dr. Wood Made Director Emeritus.—Dr. Francis Carter Wood has been made director emeritus of the Institute of Cancer Research at Columbia University College of Physicians and Surgeons. He will continue in private practice. It was also announced that the institute has been converted into the department of cancer research of the medical school, with Dr. William H. Woglom, associate professor of cancer research, as acting executive officer of the department. Dr. Wood, an Ohioan, graduated at Columbia in 1894 and has been a member of its teaching staff since 1896, becoming professor and director of the Institute of Cancer Research in 1912. Dr. Woglom was born in Brooklyn and received his degree in medicine at Columbia in 1901. He was associated with the city department of health, 1908-1909; served as assistant to the director, Imperial Cancer Research Fund, London, England, 1911-1912, and assistant professor of cancer research at the Columbia institute from 1912 to 1917, when he was made associate professor of cancer research at the medical school.

Dr. Goldwater President of Associated Hospital Service.—Dr. Sigismund S. Goldwater has accepted the presidency of Associated Hospital Service of New York, sponsor of the "three cents a day" plan. He will continue to serve as commissioner of hospitals of the city until relieved by the mayor. Mr. David H. McAlpin Pyle, chairman of the board and vice president of Associated Hospital Service, has been acting as president. He will continue as chairman of the board. The service is a nonprofit organization and now has more than a million and a quarter subscribers in seventeen counties in New York State, including the metropolitan area. The "three cents a day" plan was organized five years ago. Dr. Goldwater graduated at University and Bellevue Hospital Medical College, New York, in 1901. He served as superintendent of Mount Sinai Hospital from 1903 to 1916 and as a director from 1917 to 1929. He was commissioner of health of the city of New York in 1914 and 1915, becoming consultant in health and hospital administration to the board of estimate in 1916 and commissioner of the department of hospitals in 1934. Dr. Goldwater was president of the American Hospital Association in 1908 and of the American Conference of Hospital Service from 1924 to 1926.

OHIO

State Medical Election.—Dr. Harry V. Paryzek, Cleveland, was chosen president-elect of the Ohio State Medical Association at its annual session in Cincinnati, May 14-16, and Dr. William M. Skipp, Youngstown, was installed as president.

Society News.—Dr. John D. Garvin, Pittsburgh, addressed the Summit County Medical Society, Akron, May 7, on "Changing Concepts of Peptic Ulcer."—Dr. John M. Sheldon, Ann Arbor, Mich., addressed the Academy of Medicine of Toledo and Lucas County, May 10, on "Common Allergic Manifestations and Their Treatment." Dr. Samuel J. Levin, Detroit,

addressed the academy, May 17, on "Allergic Dermatoses." Dr. Raymond H. Quade, Toledo, was the speaker, May 24, on "Role of Surgery in Treatment of Hypertension."—Clarence C. Little, Sc.D., Bar Harbor, Maine, addressed the Academy of Medicine of Cleveland, May 17, on "Recent Advances in Cancer Research." The academy held an art and hobby exhibit at this meeting.—Dr. Morris Edward Davis, Chicago, addressed the Montgomery County Medical Society, Dayton, May 17, on "Diagnosis and Treatment in Bleeding Latent Pregnancy."

OKLAHOMA

State Medical Election.—Dr. Finis W. Ewing, Muskogee, was named president-elect of the Oklahoma State Medical Association at its forty-eighth annual session in Tulsa, May 6-8. Dr. Henry H. Turner, Oklahoma City, was installed as president. Dr. William A. Tolleson, Eufaula, was elected vice president.

Physician Honored.—On the fiftieth anniversary of his graduation from medical school, Dr. Joseph S. Fulton, Atoka, was recently honored in a ceremony in McAlester as a part of the meeting of the South Eastern Medical Society. Dr. Fulton was presented with a bronze plaque bearing the inscription "Joseph Samuel Fulton, M.D., 1890-1940. Fifty Years of Service to Humanity and Organized Medicine." Dr. Fulton is at present a councilor of the state association. He became a member of the Indian Territory Medical Association in 1891 and has held office in the state association continuously for twenty-five years. He has missed only two meetings of the state association since its organization in 1906.

PENNSYLVANIA

District Meeting.—The Eighth Councilor District Medical Society held its annual meeting in Warren, June 5. Dr. A. Follmer Yerg, Warren, president of the Warren County Medical Society, gave the address of welcome. Participating in a symposium on diabetes were Drs. Belford C. Blaine, Pottsville; George Booth, Pittsburgh; Frank A. Evans, Pittsburgh; and Edward W. Alton Ochsner, New Orleans. At this meeting testimonial certificates from the Medical Society of the State of Pennsylvania were presented to the following physicians in the eighth councilor district having practiced fifty years:

Dr. Myron A. Bailey, Jamestown, Mercer County, fifty-one years.
Dr. Michael V. Ball, Warren, Warren County, fifty-one years.
Dr. Otis S. Brown, Warren, Warren County, fifty-four years.
Dr. Burg Chadwick, Smethport, McKean County, fifty-two years.
Dr. Glennis E. Humphrey, Cambridge Springs, Crawford County, fifty-one years.
Dr. Hugh Jameson, Titusville, Crawford County, fifty-one years.
Dr. Andrew J. Mitchell, Sharon, Mercer County, fifty-two years.
Dr. Hiram B. Russell, Sheffield, Warren County, fifty years.
Dr. Monroe T. Smith, Warren, Warren County, fifty years.

The woman's auxiliaries of the district also met in annual session at this time.

Philadelphia

"Medicinal Garden" Dedicated.—A "Medicinal Herb Garden" was formally opened in the "back yard" of the College of Physicians, May 23. A tea and inspection of the garden with its growing herbs marked the event. Newspapers reported that it was not until the college moved to its present quarters that the dream of one of its founders, Dr. Benjamin Rush, was realized with the development of a well planned medicinal plant garden. Dr. Rush was said to have suggested at one time the need for a medical library and a medicinal herb garden. An ivy covered brick wall encloses the garden, and planting centers about an astrolabe, which is the gift of Mrs. Alfred Stengel.

Society News.—Speakers before the Philadelphia County Medical Society, May 8, were Drs. John R. Paul, New Haven, Conn., on "Recent Developments in the Epidemiology of Poliomyelitis"; Henry F. Hunt, Danville, "Brucellosis," and Hobart A. Reimann, Philadelphia, "Spotted Fever in Southeastern Pennsylvania." The society held a special meeting, May 2, in observance of Child Health Week, with discussions of immunization, nutrition of the child, habits and training and a panel discussion followed by questions from the audience. The public was invited to this meeting.—Dr. Robert B. Osgood, Boston, gave the Nathan Lewis Hatfield lecture of the College of Physicians of Philadelphia, May 1, on "The Medical and Social Approaches to the Problem of Chronic Rheumatism."—Drs. Louis Kaplan and James A. Lehman addressed the Philadelphia Academy of Surgery, May 6, on "Observations on the Relationship of the Scalenus Anticus to Shoulder Pain" and "Prevention of Complications in Thyroid Surgery" respectively.

The Annual Thomas McCrae Award.—Announcement is made of the Thomas McCrae Award to be given annually at the Pennsylvania Hospital, Philadelphia, to perpetuate the memory of the late Dr. Thomas McCrae and to encourage clinical investigation. All members of the professional staff of the Pennsylvania Hospital, except chiefs of service and directors of departments, are eligible to compete for the \$100 award. In case of co-authorship the award is to be divided among the eligible candidates submitting the most worthy original observations made at and published from the Pennsylvania Hospital. The first award will be given for publications appearing in 1940. Four reprints of each publication to be considered must be submitted to the committee before January 15 of each year, the award to be presented at a special scientific meeting in March of each year. The award committee will consist of three members, two of whom shall be selected from two outside institutions and have no official connection with the Pennsylvania Hospital. Dr. McCrae, who died in 1935, had been professor of medicine at Jefferson Medical College of Philadelphia from 1912 until his death and concurrently physician to the Pennsylvania and Jefferson hospitals. He was chairman of the Section on Practice of Medicine, American Medical Association, 1914-1915.

TENNESSEE

Society News.—Dr. William Wesley Wilkerson Jr., Nashville, was elected president of the Tennessee Academy of Ophthalmology and Otolaryngology at the recent annual meeting in Chatanooga. Dr. James V. Hodge, Kingsport, was elected vice president and Dr. William D. Stinson, Memphis, reelected secretary.—Drs. Burnett W. Wright and John Howard King, Nashville, addressed the Nashville Academy of Medicine and the Davidson County Medical Society, Nashville, May 14, on "Radical Prostatectomy for Carcinoma" and "Neurodermatitis" respectively.—Speakers at a meeting of the Dyer, Lake and Crockett Counties Medical Society, Dyersburg, May 1, were Drs. James B. Cochran, Dyersburg, on "Liver Abscess"; James Wesley McKinney, Memphis, "Corneal Transplantation and Eye Conditions in General Practice," and Thomas M. Jordan, Alamo, "Syphilis in General Practice."—Dr. Hal McCluney Davison, Atlanta, Ga., addressed the Chattanooga and Hamilton County Medical Society, April 26, on "Neuroses from the Standpoint of General Medicine."—Dr. John S. Freeman, Springfield, addressed the Robertson County Medical Society, Donelson, April 16, on typhus fever.—Dr. Byrl R. Kirklin, Rochester, Minn., addressed the Memphis and Shelby County Medical Society, April 16, on "Bleeding Lesions of the Gastrointestinal Tract."—Dr. Ernest R. Zemp, Knoxville, addressed the Knox County Medical Society, Knoxville, April 30, on "The Use of Diuretics in Bright's Disease."

VERMONT

New England Obstetrical Meeting.—The spring meeting of the New England Obstetrical and Gynecological Society was held at Burlington, June 12. Clinics were conducted at the Mary Fletcher Hospital. The program also included a symposium on pelvic trauma and relaxations with the following speakers, all from Burlington:

Dr. Herbert A. Durfee, Obstetrical Conservation of the Birth Canal; Episiotomy, Secondary Repairs.
Dr. Benjamin F. Clark, Restoration of the Birth Canal; Anterior and Posterior Plastic Operations, and the Kennedy Operation for Urinary Incontinence.
Dr. Edward D. McSweeney, Prevention and Treatment of Retroversion.
Dr. Oliver N. Eastman, Surgical Cure of Uterine Prolapse.

WASHINGTON

Refresher Course in Obstetrics.—Drs. Harold M. Teel, instructor of obstetrics and maternal health, Harvard School of Public Health, Boston, and Dr. Charles F. McKhann, associate professor of pediatrics and communicable diseases at Harvard, will deliver refresher lectures in obstetrics in Seattle, July 8, according to the *Bulletin of the King County Medical Society*.

Society News.—Dr. Edward C. Rosenow, Rochester, Minn., addressed the King County Medical Society, Seattle, at a special meeting, May 28, on "Focal Infections." At a regular meeting, June 3, the speakers were Drs. Edward A. LeCocq, on "Analysis of End Results in the Nailing of Fracture of the Neck of the Femur"; Louis H. Edmunds, "Repair of Skin Defects Associated with Fractures and Bone Lesions," and Darrell G. Leavitt, "Painful Feet: Fundamental Principles in Diagnosis and Treatment."—Dr. George W. Cornett, Yakima, was elected president of the Washington State Radiological Society at the annual meeting in Seattle, May 3, and Dr. Ken-

neth J. Holtz, Seattle, secretary. — Drs. Paul Bailey and Roger H. Keane, Portland, Ore., addressed the Cowlitz County Medical Society, Longview, in April on the use of the bronchoscope and a new type of gastroscope.

GENERAL

Request Letters Written by Dr. Abel.—The letters and papers of the late Dr. John J. Abel, professor emeritus of pharmacology, Johns Hopkins University School of Medicine, Baltimore, have been deposited in the Institute of Medicine of Medicine at the university for cataloguing. The institute would welcome any letters written by Dr. Abel prior to 1915 and will return them promptly after they have been transcribed. Please communicate with Miss Helen T. Konjias, 1900 East Monument Street, Baltimore.

American Physiotherapy Association.—The nineteenth annual convention of the American Physiotherapy Association will be held at the Hotel Biltmore, New York, June 23-28. Among the New York speakers will be:

- Dr. Irving S. Wright, New York, Treatment of Peripheral Vascular Diseases.
- Dr. William Bierman, New York, Pathology of Peripheral Vascular Diseases.
- Dr. Barbara B. Stimson, New York, Fractures.
- Dr. Robert Lee Patterson Jr., Kerwin Armand Fischer and Florence K. Winter, B.S., New York, Erb's Palsy.
- Dr. William Benham Snow, New York, Electrical Muscle and Nerve Testing.

The program also includes round table discussions on cerebral palsy and education, scoliosis clinic, and symposium on arthritides.

Home Study Courses in Ophthalmology and Otolaryngology.—The American Academy of Ophthalmology and Otolaryngology announces the establishment of home study courses in the fundamentals of ophthalmology and otolaryngology, to begin August 1. Any graduate physician and otolaryngologist who has completed a rotating internship or its equivalent, who has committed himself in writing to the secretary of the academy that he plans to enter the specialties and who plans to take the examination of one of the special boards when he is prepared. An applicant may register for courses in only one of the specialties. The fee is \$10. Registration must be made through the executive secretary of the academy, Dr. William P. Wherry, 1500 Medical Arts Building, Omaha, before July 1.

Enforcement of Standards for Surgical Catgut Postponed.—On the recommendation of the Committee of Revision of the U. S. Pharmacopoeia XII and with the approval of the board of trustees, the enforcement of the standards for surgical gut, which were announced in the second supplement to the U. S. Pharmacopoeia XI, are postponed until January 1. These standards were to become official July 1 but, because of the discovery that considerable stocks of surgical gut, conforming to the new pharmacopoeial standards with respect to their diameter, tensile strength and sterility but not labeled in accordance with the new official requirements, were still in the hands of dealers, the action herein announced was taken. Since this surgical gut could be used with entire safety it was deemed unnecessary to render the stock unsalable and therefore cause a large financial loss.

Experiments on Five Day Treatment of Syphilis.—The American Social Hygiene Association, New York, has been asked to gather and keep available information on the intravenous drip method of treatment of syphilis. The association requests all physicians and hospitals carrying on experiments with this method of treatment of syphilis to send it brief information regarding the following points:

1. Name of hospital or other institution.
2. Name of principal physician in charge of the intravenous drip study.
3. Type of case or cases of syphilis treated by the intravenous drip method.
4. Name of drug or drugs used (a) by the intravenous drip study, (b) by any other method before, during or after intravenous drip.
5. Routine laboratory therapy used.
6. Usual number of hours of intravenous drip treatment per day per patient.
7. Usual number of days of intravenous drip treatment per day per patient.
8. Any other pertinent facts.

The association will, so far as possible, answer inquiries regarding this treatment of syphilis. It has available for physicians, on request, a brief pamphlet on the present status of the intravenous drip method of treatment of syphilis. The address of the American Social Hygiene Association is 50 West Fiftieth Street, New York.

Bibliography of Pharmacology.—A new monthly bibliography is now being issued by the Hooker Scientific Library to record current literature in pharmacology. Entries are in title form but since the actual titles are often not informative a descriptive title is given to each item. Trade or common

names of remedies are identified by addition of the chemical name when possible. Items in a foreign language are given descriptive titles in English. Each entry is spaced apart from other entries so that it can be clipped for mounting on an index card. Photoprint or microfilm copies of original articles can be obtained at small expense from the Hooker Scientific Library, or an abstract of any item will be supplied for a nominal fee. Every foreign language entry carries a statement showing the cost of a complete translation. A specimen copy of the "Bibliography of Pharmacology" and detailed information concerning the library and its work can be had by writing to Hooker Scientific Library, Central College, Fayette, Mo.

The Ashford Award in Tropical Medicine.—At the annual meeting of the American Society of Tropical Medicine in Memphis, Tenn., the Bailey K. Ashford Award in Tropical Medicine was established by Eli Lilly & Co. to be awarded on alternate years for a total of three times. The award will be \$1,000 and a bronze medal suitably engraved. An additional amount of \$150 or as much thereof as may be necessary is available toward traveling expenses for the recipient into considered research in the field of tropical medicine, taking into consideration independence of thought and originality. The award must be a citizen of the United States and less than 35 years of age on January 1 of the year in which the award is made. The recipient must not be associated with a commercial laboratory and need not be a member of the American Society of Tropical Medicine. Members of the American Society of Tropical Medicine are to submit to the secretary of the society in triplicate the name of a proposed recipient with information concerning his personality and training and a statement of the research work for which the award is to be made. All nominations must be in the hands of the secretary at least sixty days before the dates of the annual meeting and given opportunity to present a short review of his work at the meeting. The committee of award shall consist of the president of the society ex officio and three members of the society, each to serve for a period of six years, one to be elected every other year at the annual meeting by the council, except that the original committee be elected at once by the council on nomination of the president, one member to be elected for six years, one for four years and one for two.

Results of the Golf Tournament at New York.—At the twenty-sixth annual tournament of the American Medical Golfing Association, at Winged Foot Golf Club, Mamaroneck, N. Y., Monday, June 10, in a field of 145 golfers, Dr. John Murphy, Detroit, won the championship with a gross of 160 for thirty-six holes and at the banquet was presented with the Will Walter Trophy. The runner-up was Dr. G. R. Love, Oconomowoc, Wis., with a score of 162. Dr. Love was awarded the St. Louis Trophy. Other winners in the thirty-six hole event were Drs. C. E. Moore, Harrisburg, Pa.; F. O. Henrickson, Springfield, Pa.; J. C. Cox, Maplewood, N. J.; E. B. Sullivan, New York City; E. S. Edgerton, Wichita, Kan., and J. J. Marek, Cleveland, Ohio. Dr. D. H. Houston, Seattle, and Dr. R. J. Vreeland, Paterson, N. J., were tied for the thirty-six hole Handicap Championship. On the toss, Houston won the Detroit Trophy and Vreeland won the president's cup. Other winners in the handicap championship fight were Drs. A. M. Paulson, Plainfield, N. J.; R. M. Wolff, Lebanon, Pa.; W. C. Spiedel, Seattle; P. H. Watson, Newburgh, N. Y.; C. G. Prather, Westwood, N. J.; Dr. J. J. Hennessy, Hartford, Conn.; Dr. J. J. Hennessy, Hartford, Conn., won the eighteen hole championship, gaining the Golden State Trophy. The eighteen hole handicap championship went to Dr. R. L. Cox, Starr Junction, Pa., who won the Ben Thomas Trophy. Second place went to Dr. J. M. Robb, Detroit, who took home the Atlantic City Trophy. In the Maturity Event the Minneapolis Trophy went to Dr. Frank A. Kelly, Detroit.

Dr. Charles Lukens, Toledo, Ohio, won the Wendell Phillips Trophy, emblematic of championship among the past presidents of the American Medical Golfing Association. Dr. D. H. Houston was elected president, Dr. Harry E. Mock of Chicago, first vice president, and Dr. James Craig Joyner, New York City, second vice president of the A. M. G. A. Bill Burns, Lansing, Mich., was reappointed executive secretary. Dr. Hall, the retiring president, was made a member of the board of directors. The next tournament will be held in Cleveland in June 1941.

Traumatic Shock

Until recently, surgeons and physiologists were in accord regarding shock, considering it a condition accompanying traumatic toxemia. This agreement has not withstood the impact of recent investigations on histamine or on the vasomotor tonus and the biochemical humoral changes. The recent work of Frank C. Mann and his collaborators has led to some conclusions. A large number of men are found at the front with a treacherous syndrome characterized by vasomotor, circulatory and psychic insufficiency, the result of a series of diverse syndromes due to hemorrhage, emotion, pain and fatigue and to toxic and infectious absorption. Shock so defined is a complication involving depression and toxemia. It is frequently fatal. Aid must quickly be given to the wounded before complications and the critical moment occur which set the vicious circle of shock in motion. We now have a series of new therapies. Prophylaxis consists in providing proper food and care and in administration of respiratory and cardiovascular analeptics, to which might be added atropine, strychnine and picrotoxin, not to mention oxygen. Preventive therapy may be adapted to certain conditions such as hemorrhage, nervous exhaustion and gas poisoning. Curative therapy consists in restoring body temperature, maintaining the activity of the cardiovascular system by physiologic serum employed in moderation and a constant check of the venous pressure. Acidosis must be combated by sodium bicarbonate and anoxemia by oxygen. Besides, certain manifestations will control therapy and make mandatory transfusions in cases of hemorrhage, of blood stagnation and of complete paralytic vasodilatation. These are the views recently presented by G. Janneney and L. Justin-Besançon before the Academy of Surgery. Two significant facts appeared: The garrot retards the appearance of shock; amputation cures it, even if performed during complete and grave shock. The role of absorption of proteins devitalized by the trauma is thus brought out. Léon Binet and M. V. Strumza obtained good results in grave experimentally induced hemorrhage by means of a mixture of three parts of serum saturated with oxygen and one part of citrated blood. However, a hemorrhage is not a traumatic shock. Lambret, who was to make a report on shock before the Congress of Surgeons which was to take place in Stockholm in 1941 but has been canceled, stressed two principal factors in the origin of shock: one an immediate neurovegetative factor whose point of departure was the wound, with multiple small filaments of the sympathetic nerve; the other a delayed toxic factor caused by the pressure of liberated proteins in the blood. Lambret concluded that the essential remedies against shock consisted in transfusions in large quantities and large doses of insulin. However, he realized that further investigations were needed.

Typhus Fever

Danielopolu and his collaborators during and after the war of 1914-1918 observed widespread typhus epidemics in the Orient. Recently they pointed out before the Academy of Medicine that war epidemics furnished the gravest cases. Typhus seems to become intensified by passing successively through the bodies of individuals and disease vectors. Russia constituted the great virus reservoir. The principal characteristic of the infection was its localization in the vascular system, where lesions manifested themselves in conjunctival injections and vasodilatation of the face followed by lesions of the walls of the vessels. These were succeeded by "syndromes of the extremities" and myocardiac, renal and nervous disorders. Danielopolu said that

in hypertrophic cases one could find as many as 100,000 leukocytes and in fatal cases as many as 126,000. Two abnormal factors were present: plasmocytes with basophilic protoplasm and monocytoïds of endothelial or reticulo-endothelial origin that sprang from vascular desquamation and possessed great diagnostic value. Rapid increase of leukocytes carried with it a fatal prognosis. Simultaneously there appeared changes in the cerebrospinal fluid, such as leukocytic reactions, red blood corpuscles and xanthochromia.

Typhus fever as well as relapsing fever was transmitted, he said, by the body louse. Infections could be caused by the crushing of lice in contact with the skin or by touching the conjunctiva with contaminated fingers. Lice feces also played a certain part, but the bite of the insect introduced the virus into the blood. In this way the occasional occurrence of typhus among physicians and nurses was to be explained. The presence of many lice was needed to spread relapsing fever, but a few sufficed to cause typhus, if they carried the infection. This explained certain epidemiologic phenomena, for example the clear distinction between the evolution of the two kinds of epidemics. In case of a combined epidemic a widely practiced delousing caused relapsing fever almost to disappear entirely, while typhus persisted because it required fewer disease carriers.

The viability of typhus virus was considerable and often bridged the intervals between epidemics. M. Balthazard and G. Blanc reported to the Société de pathologie exotique experiments with lice excrements, the infectivity of which was retained for more than 300 days. Dried virus could thus be transported in the baggage and the clothes of refugees. These authors pointed out that the infection of rat fleas by the virus of epidemic typhus coincided with that of the body louse by the same virus and that of fleas by the virus of rat typhus. Paul Durand and Paul Giraud discussed before the Academy of Science their methods of antityphus vaccination by means of a fine emulsion of mouse lungs infected by way of the respiratory organs; that is, an emulsion of rickettsiae killed by a solution of formaldehyde. They demonstrated the harmlessness of the injections in all cases and the total absence of virulence in the vaccine.

Scientific Cooperation with Germany

Scientific cooperation between Germany and Hungary, Yugoslavia, Bulgaria and Greece is shown by the exchange of students carried out last summer. The summer courses held in Germany under the direction of Prof. Walter Lörch were a great success. From Hungary twenty-seven students, from Yugoslavia thirty-six, from Bulgaria nineteen and from Greece twenty-two took the exchange courses. The majority were medical and veterinary students, but there were many agricultural students. During their stay in Germany they performed, besides theoretical studies, practical work in clinics, hospitals and model farms and in the summer camps of the youth labor service.

Similarly German students visit the Southeastern European countries every summer. They are provisionally trained for this excursion at the academy in Leipzig. This scientific exchange of students between Germany and the Near East has been going on for five years. After the completion of these courses every student is obliged to write a treatise on what he learned. This academic exchange is directed by the Mittel-Europa Institute in Dresden, Germany, which has branches in the capitals of all countries concerned.

The Law on Artificial Abortion

Up to the present every physician had a right to induce abortion in case of danger to the life of the mother. Without any formality, he was obliged only to bring the act to the notice

of the public prosecutor in a confidential way. In all cases in which there was no immediate danger to life, preliminary authorization by the prosecutor was necessary and was issued on the basis of the opinion of another physician. On the ground of the registration books of the prosecutor's office the ministry of justice established the fact that in certain parts of the country the number of such operations was very great. The suspicion arose that it is very easy to procure medical certificates recommending the performance of abortion. On this ground the minister of justice modified the law. The prosecutors have been instructed to give permission only (1) if there is danger to the mother's life which cannot be averted in any other way; (2) if pregnancy aggravates the disease of the woman and there is no other way to avert the danger; (3) if one of the parents is suffering from insanity. The prosecutor issues the permission by observing the following rules: After filing the doctor's application for permission, the prosecutor on duty and the forensic doctor appear in the home of the pregnant woman and the latter examines her. The imminent danger having been established, the permission is issued. In instances described in paragraphs 2 and 3 the application to the prosecutor has to be supplemented by the certificate of a hospital doctor or a certificate must be issued by two physicians who have held a consultation. The consultant must be a specialist in female diseases. On receipt of the application the prosecutor appoints a medical committee consisting of the forensic doctor, a specialist of the disease from which the woman suffers and the district medical officer of health. The committee submits to the prosecutor a written report. The prosecutor handles all matters with professional secrecy as long as there is no evidence that a criminal act has been committed in connection with the operation.

New Regulations Regarding Medicines

The National Department of Hygiene in Buenos Aires has issued new regulations regarding the trade in medicaments. One is that directly underneath the name of the medicine it must be indicated whether it is obtainable without or only with prescription. Advertising has been restricted in certain respects; on the labels, in the prospectuses and in other types of printed matter that are enclosed with the medicine as well as in the advertisements, only the pharmacologic action may be mentioned, whereas it is absolutely forbidden to list diseases or clinical symptoms. This regulation applies not only to new preparations but also to those already accepted. In the case of the latter, the regulations must be complied with within one year, otherwise the permit for the marketing of the preparations in question is withdrawn. An official list contains the details regarding the pharmaceutical classification and the sale. These measures were approved by large medical and pharmaceutical groups. A large number of letters of appreciation have been published in the *Boletín Sanitario del Departamento Nacional de Higiene*.

The president of the Argentine Republic, Dr. Ortiz, has issued a regulation according to which the accumulation of medicines for speculation is prohibited.

Health Conditions in Argentina

The report of the National Health Department for 1938, issued recently, contains interesting information. Progress has been made in combating malaria; the number of patients treated was in round numbers 160,000. More than 1,800 Kg. of quinine was distributed and in addition almost 140,000 tablets of atabrine and 72,000 of plasmochin, which quantities were larger than in the preceding year. There is a special Dirección General del Paludismo, which has authority over the six northern provinces and which used for purposes of sanitation large quantities of

petroleum and paris green; moreover, drainage of swamps and other well known sanitation methods were employed. In rural regions, the campaign is difficult. It is limited mainly to the distribution of medicines free of charge. To protect nurslings, 300 cradles were acquired which are impenetrable to mosquitoes.

Of the scientific advances, there is the detection of *Anopheles annulipalpis* in Mendoza, the existence of which was formerly regarded as doubtful; its larva was hitherto unknown. Studies revealed that this is chiefly a zoophilic mosquito with only a slight tendency to attack human subjects. The endemic zone extends over 120,000 square kilometers having 850,000 inhabitants of whom 550,000 live in rural regions and 300,000 in already sanitized regions. To effect further improvements, an extensive program has been outlined.

Fifteen cases of plague with a mortality of 80 per cent were observed during 1938. In the North it is again the Dirección General del Paludismo which conducts the campaign against plague. The infection there seems to be traceable to the prevalence of the disease among the rodents of the forests, and it is probable that it entered Argentina by way of the northern boundary with Bolivia.

Fifty-three cases of smallpox were introduced from neighboring countries.

The number of new cases of leprosy was 327. The total number of leprosy patients under control at the end of 1938 was about 3,500.

Ancylostomiasis is the most important sanitary problem in a certain zone in the northern part of Argentina, especially in Corrientes. The greatest obstacle in the eradication of this endemic is that 63 per cent of the houses have no latrine.

Goiter is prevalent in some of the eastern districts; thus 27 per cent of 13,000 school children were found to have it. With the aid of school teachers, iodine therapy was extended also in the northern parts of the country, where goiter seems to be decreasing.

The protection of mother and child was extended by the establishment of additional centers in the interior of the country. The number of centers already functioning increased from seventeen to twenty-six. Consultations were given to more than 5,000 pregnant women and to 19,000 children; moreover, more than 10,000 home visits were made and 1,200,000 meals were served.

The activities of the section for the control of narcotics was continued by its director, Dr. R. A. Pita. The quantity of narcotic alkaloids imported during 1938 was considerably below the average for the preceding years. In the estimate of the requirements for 1939, the quantity for cocaine decreased by 50 per cent and that of heroin by 33 per cent, whereas that for morphine remained unchanged.

Marriages

JEFFERSON GIDEON WALDROP to Miss Lytle Rowland, both of Lewisburg, Tenn., in Louisville, Ky., recently.

THOMAS ANTHONY GARRETT, Philadelphia, to Miss Velma V. Moersdorf of Jersey City, N. J., March 25.

JOHN A. GLORIOSO, Lima, Ohio, to Miss Elsie Cahill of Halifax, Nova Scotia, Canada, February 5.

RALPH DANIEL BOLTON to DR. SARAH CURTISS, both of Canton, Ohio, in South Euclid, March 30.

JOHN TALLMAN JARRETT, Dunbar, W. Va., to Miss Anne Mildred Wood of Richmond, Va., May 1.

WILLIAM A. SCHROER, Fort Lorame, Ohio, to Miss Ellen Elizabeth Boyer of Miamisburg, May 4.

THOMAS FINDLEY JR., St. Louis, to Miss Jean Kyer of Ann Arbor, Mich., in St. Louis, April 11.

JAMES E. MURTAUGH, Charles City, Iowa, to Miss Margaret McGowan of Fort Dodge, May 25.

Deaths

Alfred James Scott Jr. * Los Angeles; University of Southern California College of Medicine, Los Angeles, 1909; member of the House of Delegates of the American Medical Association in 1934 and 1936; clinical instructor in pediatrics at the University of California Medical Department from 1909 to 1912; clinical instructor in pediatrics at his alma mater, 1912-1913, assistant professor of pediatrics from 1914 to 1918, associate professor 1918-1919 and professor 1919-1920; professor of clinical pediatrics from 1920 to 1934, professor of pediatrics and later professor of pediatrics emeritus at the College of Medical Evangelists; fellow of the American College of Physicians; past president of the Southwestern Pediatric Society and the Los Angeles Obstetrical Society; member of the California State Department of Public Health from 1922 to 1932; member of the attending staff, Los Angeles County Hospital, from 1910 to 1924 and the consulting staff from 1924 to 1936; on the staff and member of the medical advisory board from 1922 to 1937; president of the California Babies Hospital from 1920 to 1931; aged 58; died, April 17.

Charles Richard * Brigadier General, U. S. Army, retired, Washington, D. C.; University of the City of New York Medical Department, 1876; member of the House of Delegates of the American Medical Association in 1907 and 1914; entered the regular army as an assistant surgeon in 1879; served during the Spanish-American War; at various times was in command of the Army Medical School, Walter Reed Hospital, the Sternberg Hospital in Manila and the Medical Supply Depot in New York; during the World War he was one of the principal assistants in the office of the Surgeon General; from 1888 to 1889 was lecturer of military medicine and professor of surgery from 1889 to 1891 at the University of Colorado; was commissioned a colonel in 1910 and was retired in 1918 by operation of law; under the Act of June 21, 1930, was commissioned a brigadier general; aged 85; died, April 19, of coronary thrombosis, arteriosclerosis and hypertension.

Alfred Hans Waring Caulfield, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1904; past president of the Association for the Study of Allergy and the American Association for the Study of Asthma; member of the American Clinical and Climatological Association; served during the World War; associated with the department of pensions and national health; research member of the Connaught Laboratories, University of Toronto; on the staffs of the Christie Street Hospital, Toronto General Hospital and the Toronto Western Hospital; director of the pathology department, Muskoka Cottage Hospital and the Muskoka Free Hospital for Consumptives, Sanitarium; aged 60; died, May 2.

Walter Leslie Huggins * Los Angeles; Albany (N. Y.) Medical College, 1899; University of Southern California College of Medicine, Los Angeles, 1908; fellow of the American College of Surgeons; formerly associate professor of surgery at the College of Medical Evangelists; aged 68; consulting surgeon to the Los Angeles County Hospital and Orthopedic Hospital; attending surgeon to the Methodist Hospital and the Hollywood Hospital, where he died, April 18.

Clifford Weld Skinner * Meadville, Pa.; Rush Medical College, Chicago, 1930; formerly assistant dean and associate professor of anatomy at the Medical College of Virginia, Richmond; director of health, Allegheny College; member of the American Society of Anesthetists, Inc.; on the staff of the Meadville City Hospital; aged 47; died, April 22, of cerebral hemorrhage.

Clarence Worrel Prevost * Pittston, Pa.; Jefferson Medical College of Philadelphia, 1894; fellow of the American College of Surgeons; past president of the Luzerne County Medical Society; surgeon to the Lehigh Valley Railroad and the Lackawanna and Wyoming Valley Railroad; on the staff of the Pittston Hospital; aged 74; died, April 30, of heart block.

Henry Wireman Cook * Minneapolis; Johns Hopkins University School of Medicine, Baltimore, 1902; vice president and medical director of the Northwestern National Life Insurance Company; past president of the Association of Life Insurance Medical Directors; aged 62; died, April 25, of coronary thrombosis.

Edward William Hall, San Diego, Calif.; Long Island College Hospital, Brooklyn, 1897; veteran of the Spanish-American and World wars; formerly member of the board of health of New York City; for many years on the staff of the Harlem Hospital, New York; aged 79; was drowned, April 7.

Theodore James Peake, Clinton, S. C.; University of Nashville (Tenn.) Medical Department, 1906; member of the South Carolina Medical Association; served during the World War; aged 59; died, April 14, in the Veterans Administration Facility, Columbia, of peptic ulcer with massive hemorrhage.

Caleb Edwin Witt, Little Rock, Ark.; Missouri Medical College, St. Louis, 1889; Hospital College of Medicine, Louisville, Ky., 1896; emeritus professor of medicine at the University of Arkansas School of Medicine; for many years on the staff of the Baptist Hospital; aged 77; died April 23.

Reba Lloyd * Bridgeton, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1898; past president of the Cumberland County Medical Society; past president of the board of health; aged 72; owner of the Ivy Hall Sanitarium, where she died, April 14, of chronic myocarditis and arthritis.

Lewis Perley Felch * Boston; Tufts College Medical School, Boston, 1906; for many years on the staff of the Massachusetts General Hospital and the Carney Hospital; was medical examiner for the industrial accident board; aged 68; died, April 2, of arteriosclerosis and uremia.

Henry Joel Walcott * Concord, Mass.; Jefferson Medical College of Philadelphia, 1896; on the staff of the Emerson Hospital; for many years on the staff of the Massachusetts Reformatory, West Concord; aged 68; died, April 17, in the Massachusetts General Hospital, Boston.

Francis Jervois Callanan, Boston; Harvard Medical School, Boston, 1918; member of the Massachusetts Medical Society; fellow of the American College of Surgeons; aged 45; surgeon to the Massachusetts Women's Hospital, where he died, April 21, of carcinoma of the right lung.

Samuel Frank, Brooklyn; Long Island College Hospital, Brooklyn, 1904; member of the Medical Society of the State of New York; served during the World War; on the staffs of the Coney Island Hospital and the Brooklyn Eye and Ear Hospital; aged 62; died, April 5, of uremia.

Jacob J. Schloss, Boston; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1925; instructor of Medicine at Tufts College Medical School; on the staff of the Joseph H. Pratt Diagnostic Hospital; aged 41; died, April 23, of coronary thrombosis.

William Martin Millar, Westport, Conn.; Johns Hopkins University School of Medicine, Baltimore, 1927; formerly assistant professor of surgery, University of Cincinnati College of Medicine; aged 38; died, April 12, in the Duke Hospital, Durham, N. C., of Hodgkin's disease.

Alden Robbins Hoover * Elizabeth, N. J.; State University of Iowa College of Medicine, Iowa City, 1905; fellow of the American College of Surgeons; formerly a medical missionary; served during the World War; aged 63; died, April 29, of coronary thrombosis.

Clarence Prentice Rice, Breckenridge, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1906; member of the American Academy of Ophthalmology and Otolaryngology; aged 64; died, April 12, of cerebral hemorrhage and arteriosclerosis.

Martha Eleanor Lovell, Winthrop, Mass.; Woman's Medical College of Pennsylvania, Philadelphia, 1899; member of the Massachusetts Medical Society; aged 73; died, April 22, in the Peter Bent Brigham Hospital, Boston, of coronary thrombosis and arteriosclerosis.

Abraham L. Farnsworth * Baraboo, Wis.; Milwaukee Medical College, 1900; past president of the Sauk County Medical Society; on the staff of St. Mary's Ringling Hospital; aged 73; died, April 20, of chronic nephritis and chronic myocarditis.

Gilbert Alonzo Ashmun, Brooklyn; Long Island College Hospital, Brooklyn, 1895; member of the Medical Society of the State of New York; served during the World War; aged 66; died, May 2, in the Brooklyn Hospital of brain tumor.

Charles Glover Shannon, Chicago; Reliance Medical College, Chicago, 1910; served during the World War; aged 55; died, April 25, in the Veterans Administration Facility, Bay Pines, Fla., of arteriosclerotic hypertensive heart disease.

Henry Erwin Shaw, Ashland City, Tenn.; Vanderbilt University School of Medicine, Nashville, 1882; University of Nashville (Tenn.) Medical Department, 1883; aged 82; died, April 21, of lobar pneumonia and arteriosclerosis.

Gertrude Jones Cuscaden, Chillicothe, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1874; member of the Nebraska State Medical Association; aged 90; died, May 16, of myocarditis and pneumonia.

Herbert Llewellyn Mains, Danvers, Mass.; University of Vermont College of Medicine, Burlington, 1912; member of the Massachusetts Medical Society; served during the World War; aged 62; died, April 6, of coronary thrombosis.

Henry C. Bowman, Schuylkill Haven, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1890; member of the Medical Society of the State of Pennsylvania; aged 85; died, April 19, of acute coronary occlusion.

John Moody Yeager, Marlinton, W. Va.; University of Louisville (Ky.) Medical Department, 1901; aged 63; died, April 14, in the Chesapeake and Ohio Railroad Hospital, Clifton Forge, Va., of cerebral hemorrhage.

Edward Wallace Young, New Bedford, Mass.; Tufts College Medical School, Boston, 1913; member of the Massachusetts Medical Society; served during the World War; aged 53; died, April 16, of cirrhosis of the liver.

Oscar Herman Riemenschneider, Cleveland; Cleveland Homeopathic Medical College, 1903; served during the World War; aged 59; died, April 7, in the City Hospital of bronchopneumonia and acute hemorrhagic cystitis.

Fernando A. B. Roys, Syracuse, N. Y.; College of Physicians and Surgeons, Keokuk, Iowa, 1873; Chicago Medical College, 1881; aged 95; died, April 26, in the Syracuse Memorial Hospital of coronary thrombosis.

Felix M. Williams, Hot Springs National Park, Ark.; Vanderbilt University School of Medicine, Nashville, Tenn., 1891; aged 78; died, April 11, in St. Joseph's Hospital of a streptococcal infection of the throat.

Wilfred Henry Gardner, Los Angeles; Chicago Homeopathic Medical College, 1902; University of Illinois College of Medicine, Chicago, 1904; served during the World War; aged 62; died, April 24, of heart disease.

Elmer Kenneth Umberger, Flatonia, Texas; University of Tennessee College of Medicine, Memphis, 1931; at one time health officer of McCreary County, Ky.; aged 35; died, April 23, of an overdose of a hypnotic.

Walter Henry Rice @ Boston; Tufts College Medical School, Boston, 1896; Harvard Medical School, Boston, 1899; aged 67; died, April 19, in the Cambridge (Mass.) Hospital of carcinoma of the stomach.

Frederick Terrell, San Antonio, Texas; Harvard Medical School, Boston, 1881; formerly mayor, president of the school board and bank president; aged 84; died, March 11, of arteriosclerotic heart disease.

William Francis Wright @ Portsmouth, R. I.; Baltimore Medical College, 1908; member of the Massachusetts Medical Society; aged 59; died, April 11, in Miami, Fla., of gastrointestinal hemorrhage.

John Darrow Tupper, North Dartmouth, Mass.; Boston University School of Medicine, 1895; for many years school physician; aged 81; died, March 4, in the Fall River (Mass.) General Hospital.

Alexius Henri Archambault, Montreal, Que., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1909; aged 53; died, March 24.

Paul Wayne Butz, Plymouth, Mich.; Northwestern University Medical School, Chicago, 1929; member of the Michigan State Medical Society; aged 39; was killed, May 1, in an automobile accident.

William A. Chapman, Miami, Fla.; Meharry Medical College, Nashville, Tenn., 1913; aged 53; died, April 30, of septicemia following abscess of the right hip joint due to an automobile accident.

Frank Sherman Kitson @ North Manchester, Ind.; Rush Medical College, Chicago, 1895; aged 69; died, April 25, in the Washash (Ind.) County Hospital of cardiovascular renal disease.

Herbert Cooper, Drexel Hill, Pa.; Jefferson Medical College of Philadelphia, 1903; served during the World War; aged 66; died, April 10, of cardiac embolism and diabetes mellitus.

James Wesley Pollard, Homelake, Colo.; Memphis (Tenn.) Hospital Medical College, 1904; member of the Colorado State Medical Society; aged 65; died, April 8, of pulmonary abscess.

George Sinclair Gordon, Vancouver, B. C.; McGill University Faculty of Medicine, Montreal, Que., 1897; member of the North Pacific Surgical Association; aged 71; died, April 16.

John Cotton, Burnt Hills, N. Y.; Harvard Medical School, Boston, 1871; member of the Medical Society of the State of New York; aged 90; died, April 27, of chronic myocarditis.

Milton Ross Keeley, Los Angeles; Rush Medical College, Chicago, 1886; veteran of the Spanish-American War; aged 76; died, April 2, of chronic myocarditis and nephritis.

Edmond William Parsons, San Francisco; Cooper Medical College, San Francisco, 1905; aged 58; died, April 30, in St. Mary's Hospital of hypertension and arteriosclerosis.

Martin William Curran, Chatsworth, N. J.; Long Island College Hospital, Brooklyn, 1896; served during the World War; aged 73; died, April 17, of angina pectoris.

Daniel Livingston Morrison, New Brunswick, N. J.; New York University Medical College, 1897; aged 64; died, April 1, of arterial hypertension and myocarditis.

Reuben Baston Dearborn, Miami Beach, Fla.; Medico-Chirurgical College of Philadelphia, 1902; aged 59; died, April 17, in the Mound Park Hospital, St. Petersburg.

Nathan Cohen @ Brooklyn; Long Island College Hospital, Brooklyn, 1909; on the staffs of the Greenpoint and Beth Moses hospitals; aged 57; died, May 5, of carcinoma.

Daniel William Boden, Pasadena, Calif.; Eclectic Medical College of the City of New York, 1884; aged 82; died, April 1, of cerebral hemorrhage and diabetes mellitus.

Alexander S. Barger, Washington, D. C.; Howard University College of Medicine, Washington, 1894; aged 74; died, May 1, of arteriosclerosis and hypertension.

Karl Steinbeck, Parkersburg, W. Va.; College of Physicians and Surgeons, Baltimore, 1905; aged 58; died, April 20, in the Camden-Clark Memorial Hospital.

Llewellyn J. Sanders, Rochester, N. Y.; New York Homeopathic Medical College and Hospital, 1895; aged 67; died, April 6, of chronic bronchiectasis.

Alphonse Ames Kergosien, Bay St. Louis, Miss.; University of Louisville (Ky.) Medical Department, 1909; aged 59; died, April 23, of chronic encephalitis.

Clark Everett Baker @ Marion, Ill.; Vanderbilt University School of Medicine, Nashville, Tenn., 1917; aged 47; died, May 14, of pneumonia and heart disease.

Henry B. Curtis, Denver; Gross Medical College, Denver, 1893; member of the Colorado State Medical Society; aged 74; died, May 4, of bronchopneumonia.

Roscoe Campbell, Toronto, Canada; University of Toronto Faculty of Medicine, 1910; aged 53; died, April 8, in the Toronto Western Hospital.

C. H. McCaslin, Kansas City, Mo.; Kentucky School of Medicine, Louisville, 1881; aged 87; died, April 29, of arteriosclerosis and hypertension.

Hugh Henry Graham, Fenelon Falls, Ont., Canada; Trinity Medical College, Toronto, 1882; M.R.C.S., England, 1884; aged 85; died, March 25.

Anngnette Fowler Noble @ Westfield, Mass.; Woman's Medical College of Baltimore, 1893; aged 79; died, April 30, of coronary thrombosis.

MISBRANDED "PATENT MEDICINES" Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Benaris.—Benaris, Cleveland. Composition: Essentially liquid petrolatum, camphor and ephedrine. Fraudulently represented as an effective treatment for coughs, nasal catarrh, sinusitis, hay fever, sleeplessness, blurred vision, pains in the sides and heart, headaches from alcoholic indulgence, and many other disorders.—[N. J. 30644; November 1939.]

Gordon Red Liniment.—McConnon & Co., Winona, Minn. Composition: Essentially a small amount of camphoraceous material and red pepper in a solution of carbital (ethyl ether of diethylene glycol) and water, colored with a red dye. For earache, simple throat irritations, toothache, colic and casual swellings from congestion. Fraudulent therapeutic claims.—[N. J. 30648; November 1939.]

Neu-Life.—Health Laboratories, Sacramento, Calif. Composition: Essentially plant material including small percentages of calcium, magnesium, iron, iodine, sulfur, phosphorus, potassium and sodium. Adulterated because falsely declared to contain vitamin D; misbranded because labeled "Contains No Drugs" and because product fraudulently represented "to imbue the user with new life, to build up a new health and happiness, and to overcome glandular weakness and nerve prostration."—[N. J. 30622; November 1939.]

Normal Nux.—Norden Laboratories, Lincoln, Neb. Composition: Not more than 11 grains of strychnine and brucine sulfates per fluid ounce. Adulterated and misbranded because represented on the label to contain 14.6 grains of these substances.—[N. J. 30620; November 1939.]

San-O-Sen Antiseptic Spray.—San-O-Sen Laboratories, Chicago. Composition: Essentially water, pine oil, soap and a small amount of glycerin. For skin irritations. Fraudulent therapeutic claims.—[N. J. 30640; November 1939.]

Zilatone.—Drew Pharmacal Co., Buffalo. Composition: Tablets containing phenolphthalein, bile salts, pepsin, pancreatin and extracts of plant drugs, including red pepper, nux vomica and a laxative. Fraudulently represented to increase the digestion, stimulate the liver and bile, remedy chronic constipation, certain forms of gallbladder disorders, including gallstones; to relieve intestinal putrefaction and other bowel disorders.—[N. J. 30625; November 1939.]

JAMAICA "SPECIALIST" OFFERS A "RUPTURE CURE"

But U. S. Post Office Turns Thumbs Down

The mail-order quacks have promoted "cures" for cancer, tuberculosis, anemia, psoriasis, diabetes, Bright's disease, arteriosclerosis, high blood pressure, baldness, crooked noses and complexion ills. The entire catalogue is too long to list here! Among the treatments that obviously must be administered to the patient in person is one for hernia; yet some exploiters brazenly claim that rupture is something that can be cured by mail!

One of these gentry, an H. F. Pettitt of Kingston, Jamaica, British West Indies, advertised:

"RUPTURE CURED PERMANENTLY. SENSATIONAL! H. Pettitt (Specialist)"

When the United States Post Office investigated this enterprise, it learned that persons who answered the advertisement received printed form-letters reading in part as follows:

A NEW ERA HAS DAWNED FOR THE RUPTURED PERSON

H. F. PETTITT (SPECIALIST) INVENTOR OF THE JIFFY STOPPER—FOR THE RELIEF AND CURE OF RUPTURE

The new cure for hernia (rupture) is to close the opening where the bowels get through which cause the swelling, by a scientifically constructed device which is entirely different from anything else known for

the treatment of rupture. This wonderful device, the "Jiffy Stopper," contracts the opening by thickening the tissues, strengthening the walls and muscles, eventually closing the opening entirely—thus making a CURE of hernia. The Jiffy Stopper has the indorsement of physicians, the Chamber of Commerce of Jamaica, the Jamaica Imperial Association, and ruptured persons everywhere as the only reliable gadget for hernia.

According to the Post Office memorandum on this case "The device sold in the scheme is a simple truss which is made of a wire spring, a leather strap, and two covered composition pads, one on each end of the wire spring so that one will cover the hernia and the other will provide counter pressure on the buttocks."

Expert medical evidence was introduced at the hearing of this case to show that the proper treatment of a common inguinal hernia is the tightening of the stretched or strained lining of the abdomen and also a tightening of the ligamentous structures of the abdominal wall. The medical evidence further showed that the "Jiffy Stopper" would not thicken the tissues of the hernial opening or strengthen the walls and muscles "eventually closing the opening entirely," as represented by the promoters of this scheme. This representation, therefore, was declared to be false and fraudulent. Hence to set forth the device as a cure for all ruptures "in a short time" or in any length of time was shown to be a dishonest practice, as was the claim that by the wearing of the Jiffy Stopper "it is impossible" for the hernia to slip out of place. Accordingly a fraud order was issued on Aug. 14, 1939, against the names H. F. Pettitt, H. Pettitt, Specialist, and H. F. Pettitt, Specialist, debarring this individual and his scheme from the United States mails.

Correspondence

GALLSTONES IN CHILDREN

To the Editor:—In the article entitled "Gallstones in Children" by Seidler and Brakeley (THE JOURNAL, May 25, p. 2082) no mention is made among the etiologic factors of the hemolytic anemias—spherocytic ictero-anemia in whites and sickle cell anemia in Negroes. While by no means common, neither are these conditions extremely rare, and they should be borne in mind whenever gallstones are encountered in children. In fact, the case reported by the authors has many features which strongly suggest the presence of sickle cell anemia. A 10 year old Negro girl with a six year history of recurrent bouts of jaundice and abdominal pain who is said to have had rheumatic fever and arthralgias since and who complains now of anorexia and weakness presents the classic historical background of sickle cell anemia. The notations that she appeared to be chronically ill and that a systolic murmur was heard at the apex of the heart are features found in sickle cell anemia which, along with the history of recurrent fever and arthralgias in the past, frequently cause a faulty diagnosis of rheumatic fever to be made. The anemia and leukocytosis presented by the patient on admission are additional manifestations that characterize sickle cell anemia. Even the pericholelith lymphadenopathy on which the authors lay stress might be adequately explained by sickle cell anemia.

It would be of great interest to learn whether or not examinations were made for the presence or absence of the sickling phenomenon in the red blood cells of the patient. It would likewise be of interest to learn something more of the character of the gallstones found. If these were of the pure pigment type, the possibility of an underlying hemolytic disturbance would, to some extent, receive additional support.

There is one other feature of the laboratory data presented which merits some remark. The Van den Bergh test "both direct and indirect" is reported as "negative." I would presume that by "negative" the authors mean to convey that the "indirect

Van den Bergh test yielded a bilirubin level that was less than the maximum value, which they accept as within normal limits. The so-called indirect Van den Bergh test is in reality a quantitative estimation of the existent bilirubinemia, and as such it would make for more clarity to report it quantitatively in terms of milligrams per hundred cubic centimeters of serum rather than to employ such nondescript terms as "negative" or "positive." It is, moreover, a little difficult to understand why a patient who is clinically jaundiced and who has an icteric index of 25 should have a bilirubinemia within normal values.

J. EDWARD BERK, M.D., Philadelphia.

LABELING AND DEMOCRACY

To the Editor:—The April 27 issue, page 1671, comments on the labeling of vitamin-containing alcoholic beverages. It is undoubtedly a bad thing that the public should be misled with regard to vitamins in beverages or foods. On account of the publicity that vitamins have received, the public undoubtedly has a general idea that anything that contains vitamins must therefore be desirable.

I do not think, however, that one can defend a ruling which states that a label on a beverage or anything else should not contain truthful information concerning that material. It would certainly be proper to make a ruling forcing the manufacturer to put on the label the actual quantity of vitamins present, and it would be proper to prevent the appearance on the label of any misleading therapeutic claims.

It appears to me that this is an example of the paternalistic tendency of government bureaus. It is undoubtedly good for the health of the public that it should be protected, but whether it is good for our political future that government bureaus should interfere with the people's rights to a knowledge of the truth, and their freedom to act on that knowledge, even when one suspects that they may not act wisely, if carried to its logical conclusion leads to benevolent despotism. In these days when we are fighting so hard for the preservation of democracy, I much dislike to see such small nibblings at the margins of democracy.

R. R. NEWELL, M.D., San Francisco.

INJECTION OF VARICOSE VEINS

To the Editor:—Drs. Dean and Dulin have reported two fatal cases of pulmonary embolism following injection of varicose veins (THE JOURNAL, April 6, p. 1344). They do not state whether other nonfatal cases of embolism occurred in their total of 600 cases. The mortality of this accident is apparently high: Dean and Dulin quote Silverman's collection of twenty cases with fifteen deaths.

In one of the cases reported by these writers an interval of six days elapsed between the first and the second (fatal) embolism. During this interval the patient is described as having bronchopneumonia. Despite this consequence of embolism, might it not have been possible to ligate the external iliac vein and thus forestall the subsequent fatality? I reported such an operation, done after the second embolism (*Am. J. Surg.* 45:145 [July] 1939). It was possible with spinal anesthesia to ligate the vein above its proximal thrombosed area; no further embolism occurred.

Drs. Dean and Dulin have rightly emphasized the importance of high ligation of the saphenous vein prior to injection of varicosities.

K. P. A. TAYLOR, M.D.,
Puerto Armuelles, Chiriqui,
Republic of Panama.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

INDUSTRIAL SAFETY GLASSES

To the Editor:—The question has arisen, regarding so-called safety spectacles used in industry, as to the relative quality of flat and 6.00 curve lenses. This is especially directed to the perfection to which these lenses are ground or polished for use by a workman who does not require a correction. I am particularly interested in the comparison of the merits of flat versus curved lenses. Many workmen complain that the curved lens causes headache. I would appreciate any information regarding this subject.

R. M. Brown, M.D., Buffalo.

ANSWER.—The lenses in industrial safety glasses are most commonly of the tempered variety, and except for increased thickness and case hardening they are identical in quality and finish with standard, first quality ophthalmic lenses. Case hardening consists simply of heating the lens to a level just below its melting temperature and then cooling both surfaces simultaneously by compressed air. With a hypersensitive individual the spectacle places an annoying weight on the nose, and the reduced air circulation about the eye aggravates the discomfort of chronic conjunctivitis if present. In plano tempered lenses the deep meniscus form has effects not present in flat lenses: 1. Surface reflections are more noticeable. 2. A magnification results, though less than 1 per cent. 3. In convergence, a slight prismatic effect is produced, which may be as much as one-fourth prism diopter base out for each eye, which might be disturbing to one with more than the usual exophoria for near vision. All these effects are more likely to be ignored if a proper correcting lens is worn instead of a plano glass.

ACROPAESTHESIA

To the Editor:—A manual worker has pains in his fingers around the nails. He wears gloves at work and says that his fingers have been tender for years. There is no evidence of disease. What could cause this? What treatment should be given?

M.D., Texas.

ANSWER.—This meager description indicates acroparesthesia. If it is a typical case the attacks of pain appear more often at night or the first thing in the morning and wear off as the patient works or they are relieved by soaking the hands in warm water. They are worse in winter or if the patient has to work with cold water or handle ice. The pain may be accompanied by sensations of numbness, tingling or formication. On examination most cases prove to be hyposensitive rather than hypersensitive and show hypalgesia rather than hyperalgesia. The abnormal sensations as well as the abnormal reactions to touch and pain are general in all the fingers and are not confined to any particular nerve distribution, and there is no tenderness of the nerve trunks. In spite of the sensation of stiffness left after the attack subsides, there is never any swelling. This represents the Schultze type of acroparesthesia. The Nothnagel type is differentiated by the fact that the skin becomes blanched and cold or even cyanotic during attacks. Cassirer, an authority on this group of nervous disorders, believes that the Nothnagel group, which is not so common as the other, is an intermediate form between acroparesthesia and Raynaud's disease (Cassirer, R.: *Die vasomotorischen trophischen Neurosen*, Berlin, S. Karger, 1901).

The prognosis is good as far as concerns serious development, but the disease often resists treatment. Many cases are so mild that treatment is never sought. Cassirer mentions one case that he watched for twenty-five years without being able to see any significant progress. Spontaneous remissions occur at times.

Women between 40 and 60 years of age are most often afflicted, but when the disease occurs in men it is said to be more severe. Fine hand work, cold, trauma, anemia, excessive use of alcohol or the presence of other toxins are held responsible in some cases. In women pregnancy, the puerperium or the menopause may precipitate the disease. Psychic disturbances may be the cause in some cases. Tuberculosis and syphilis are seldom to blame. Many cases occur, however, in which no etiologic factor can be discovered.

Raynaud's disease, hysteria, neuritis, abortive forms of tetany, oncoming acromegaly, syringomyelia and ergotism have to be

differentiated. Tabes dorsalis sometimes begins with paresthesia in the extremities, but a definite nerve distribution can usually be found.

The pathogenesis of this disease is not clear. An interesting discussion of it and a report of the author's own case, caused by quinidine, is found in *Acroparesthesia and Quinidine*, a Query and a Quest, by S. E. Jelliffe (*J. Nerv. & Ment. Dis.* 79:631 [June] 1934) in which the author analyzes his case and lists the American literature on the subject.

A careful examination may reveal an underlying condition such as anemia or a mental factor that can be corrected. Rest is the logical treatment, but most cases of the disease occur in those who are compelled to work. So far as possible, exposure to cold, especially cold water or ice, should be avoided. Alcohol or other toxic factors should be eliminated. In women during the climacteric, endocrine preparations may be valuable. In cases in which no such etiologic approach is possible, electrotherapy and hydrotherapy are often of benefit. K. A. Ekblom has recently recorded success (Treatment of Acroparesthesia with Acetylcholine: Report of Twenty-One Cases, *Acta psychiat. et Neurol.* 14:311 [No. 1-2] 1939, abstr. THE JOURNAL, Dec. 2, 1939, p. 2103) with intramuscular injections of acetylcholine 0.1 Gm. daily or every other day.

heart shadow, though there is no proof of this otherwise. It should be looked for in further follow-up study. There is no cardiac tamponade evident now. Exploration for pericardial resection is as yet not in order so far as the present situation is concerned, but if more definite evidence should develop in the future of pericardial constriction, resection of the pericardium would then be advisable. There is evident also in this case a large nervous factor, perhaps associated with beginning menopause.

Some important additional information should be obtained, a new electrocardiogram, which should be abnormal, showing low voltage or low or inverted T waves if pericarditis is present, differential count of the white corpuscles to look for eosinophilia, and a follow up of the x-ray study of the heart shadow.

OVARIAN TUMORS AND ESTROGEN PRODUCTION

To the Editor:—What type of endometrium—proliferative or secretory—is usually found with the following ovarian tumors: theca cell, granulosa cell, dysgerminoma, arrhenoblastoma? Which of these tumors secrete estrogen or progesterone or both?

M.D., New York.

ANSWER.—Granulosa cell and theca cell tumors of the ovaries may be classified together, at least on the basis of similar clinical features and common genesis. Hyperplastic endometrium of the "Swiss cheese" variety is commonly found in individuals suffering with these tumors. This hyperplastic change of the endometrium is perhaps more extensively associated with granulosa cell tumors. Increased production of estrogen has been demonstrated in women suffering from either theca cell or granulosa cell tumors, and estrogen in excessive amounts has been extracted from both granulosa cell and theca cell tumor tissues.

Dysgerminomas are rare gonadal tumors often associated with pseudohermaphroditism and various types of sex underdevelopment. They elaborate no estrogenic hormone, but the preputary hormone, the follicle stimulating factor, has been found in a case recently reported in the literature. It is authoritatively stated that these tumors exert no sexual influence, but it is felt by some that they may exert weak masculinizing effects. The endometrium in cases of dysgerminoma is always hyperplastic when found in women with sexual underdevelopment. A number of cases have been reported in the literature, however, in which the uterus and its endometrium were entirely normal. Arrhenoblastomas of the ovaries exert a feminizing and masculinizing effect. The tumor secretes an abundance of the testis hormone rather than the estrogenic substance. The endometrium usually undergoes an atrophy of a type ordinarily associated with the senile uterus.

TOXIC DOSAGE OF LEAD

To the Editor:—In the answer to a query concerning the toxicity of lead in chalk (*The Journal*, Nov. 4, 1939, p. 1755), the statement was made that the usual safe limit of daily lead absorption is 2 mg. per day, in breathed air and larger amounts if taken by mouth. I should like to know the evidence on which these statements are based, particularly in view of opinion of authorities as reviewed by Calvery (*The Journal*, Nov. 5, 1938, p. 1722) that the ingestion of 0.32 mg. of lead per day was considered dangerous.

J. H. Clark, M.D., Philadelphia.

ANSWER.—A good recent discussion in the literature of the toxic dose of lead is that by Ferdinand Flurry (*Handbuch der experimentellen Pharmakologie*, Heffter and Heubner, editors, Berlin, Julius Springer 3:1575-1889, 1934) and practically all the references to this problem are there discussed. A few references, however, might be added in regard to minimal toxic doses. Dr. Blair Bell states that intravenously the smallest dose that will give symptoms is 100 mg. of colloidal lead in men and 40 mg. in women. By mouth, 5 mg. per kilogram per day for acute manifestations. For chronic manifestations, Solmann gives the figure of 0.2-0.3 mg. of lead per kilogram per day for many weeks, and other authorities all give higher figures than this. In breathing lead-contaminated air, Legge and Goadly, in their book on lead poisoning, state that 2 mg. daily breathed over a long time may cause poisoning, and this is the reference on which the usual minimal standard of lead is based. The famous drinker of lead water cited by P. Schmidt is a good example of taking lead by mouth. He drank 2.6 liters of water with a concentration of 2.9 mg. of lead per liter daily. After he had taken 5.3 Gm. of lead in two and one-half years he complained of pain in his calf muscles; after two and one-half years more, when he had taken 12.6 Gm. of lead, he had typical lead poisoning. It was well be that the amount of lead that was in the water was diminishing during these five years. It would also be of interest to look up the article by Kehoe, Thammann and Cholak in the *Journal of Industrial Hygiene* (15:306 [Sept.] 1933) in

PROBABLE POLYSEROSITIS

To the Editor:—A married woman aged 49, with four grown children, seen for the first time in August 1939, complained of a hacking, dry cough, particularly noticeable on rising in the morning. When I saw her she produced a small amount of mucus, slightly blood tinged, which I thought due to the violence of coughing. This coughing had been going on for three or four months prior to my seeing her. A poor appetite may have been a cause for a small loss in weight during the summer. Her appetite is only slightly better now and her weight is stationary at 148 pounds (67 Kg.). She is listless and weepy and she complains of having been sick a good part of her life, but after a good night's rest she is jolly. She always feels better in the morning and worse as the day passes. Noise and visitors fatigue her. She has had transient attacks of pain and aching in both shoulders, alternately and at times over the heart. Motion increases the pain, which may last two days in one shoulder joint and then disappears, reappearing in the other shoulder. So far no other joints have been involved. She had some pleural pain in the left side, followed by the development of a clear yellow transudate in the left pleural sac. Only a few plasma cells and occasional leukocytes were found in the fluid. At this time the right side was normal. I did three left pleural taps, the first two being followed by relief in coughing. Now fluid and crepitant rales have developed in the right side of the chest on auscultation. A chest plate showed general increase in lung markings on the left side and a globular heart shadow with increased shadow to the left. The cardiopulmonary ratio is 16:30. The aortic knob is not visible. Her pulse has been slow and soft. The blood pressure is around 108/70 but often goes down to 102/62. She has such a dark complexion that I at first thought she had Addison's disease. She said that about four years ago she noticed large brown blotches break out on her forearms. I have not used adrenal cortex extract. She is troubled with belching, but there is no abdominal pain except definite tenderness over the gallbladder region. Her bowels are regular once or twice a day and the stools are well formed, but she did say that during the summer she was alternately constipated and diarrhetic. There does not seem to be any fluid in the abdomen. Her extremities are normal. There are no mann reaction, and the heart tones are quiet and distant. There are no for tuberculosis was negative, as was also the Mantoux. A Wassermann and hemoglobin numbered 6,000, red blood corpuscles 5,000,000, is often subnormal and only occasionally rises to 99 F. A tenderness over the gallbladder area has lessened. I have not been able to detect any enlargement of the liver. A cholecystogram showed normal filling and emptying. An electrocardiogram done one year ago is reported to be negative. The patient had scarlet fever when a child. She says that she was quite ill and that off and on since that time she has had arthritis-like pains in the shoulders. Other details are lacking. A sister died of a stroke at 39. My impression is that this is Pick's disease, possibly originating from a rheumatic condition associated with pericardial adhesions. She has been in bed for six weeks, and I have been treating her more or less symptomatically. I have put her on salicylates for two weeks and the pain has disappeared. Recently I stopped the salicylates for two days and she again complained of pain over the heart today. I would appreciate any suggestions you might have to offer in the way of a better diagnosis and methods of treatment. Has the severing of pericardial adhesions proved helpful from the surgical standpoint?

John S. Giffin, M.D., Waterloo, Iowa.

ANSWER.—In the first place there is no indication of chronic constrictive pericarditis or so-called Pick's disease in this case. For such a diagnosis clear evidence of increased systemic venous pressure must be present with engorged neck veins, enlarged liver, and probable ascites and dependent edema. These things are not evident here. Polyserositis, however, of obscure etiology or so-called idiopathic or on the basis of disseminated lupus. From the data submitted it is impossible to determine what the polyserositis may be due to. Polyserositis itself may in time be followed by chronic constrictive pericarditis. There may well be slight pericardial effusion as suggested by the increase in the

which it is concluded that "the occurrence of lead poisoning may be expected under conditions in which lead is excreted at a mean rate above 1.1 mg. per day in the feces, and 0.21 mg. per liter in the urine." It is to be expected that conflicting views on the toxic dose of lead will continue to be held until more data are obtained by the newer chemical methods which are capable of determining quantitatively amounts of lead which would be completely missed by the older methods. Further, the susceptibility of different persons varies widely.

FREQUENCY OF URINATION IN YOUNG GIRL

To the Editor:—A girl aged 4 years had a mild laryngitis for several days in the middle of December 1939. One week later she developed frequency of urination, which is still present. The frequency is only diurnal, occurs every fifteen to forty-five minutes, and is not associated with any pain or irritation. Often just the urge to urinate is present. Physical examination revealed no abdominal masses and no dilated bladder; the external genitalia showed no inflammation or discharge present. The temperature is normal and so is the pulse rate. The patient has a good appetite and is otherwise well developed. Her fluid intake has not increased. She was hospitalized to determine the cause of the frequency. Laboratory examination revealed blood nonprotein nitrogen 30 mg., urea nitrogen 14 mg., blood sugar 90 mg. and creatinine 1.3 mg. per hundred cubic centimeters of blood. The dextrose tolerance test showed a normal curve. Urinalysis (repeated) showed albumin negative, sugar negative, no white blood cells, no red blood cells and no casts. Vaginal as well as urine smears showed the absence of organisms and trichomonas. Catheterized urine specimens revealed no growth as culture. The urine was either neutral or alkaline. The residual urine was 40 cc. The blood Kline reaction was negative. The red and white blood counts as well as the hemoglobin tests were normal. The tuberculin test (1:1,000 old tuberculin) was strongly positive, so much so that the patient's temperature increased by from 1 to 1.5 degrees for three days during the height of the reaction. A roentgenogram of the chest showed nothing abnormal. The grandmother died of tuberculous peritonitis ten months ago. The patient feels well but the frequency is still present. Please advise as to diagnosis and further laboratory procedures to determine the cause. The administration of tincture of belladonna and phenobarbital have not produced relief.

M.D., Ohio.

ANSWER:—The frequency of urination may be due to one of several causes. The history reveals that the grandmother had tuberculosis and presumably was in contact with the child. The child is said to have a strongly positive tuberculin reaction. These two facts would call for a careful investigation of the urine for the presence or absence of tubercle bacilli. It might be necessary to concentrate the urine or obtain a catheterized specimen, which could be injected into a guinea pig in a search for the tubercle bacilli.

An intravenous pyelogram or further urologic study of the bladder and genito-urinary tract might be indicated in an attempt to discover a tuberculous lesion or other abnormalities which might be the basis for frequency of urination.

Sometimes central lesions in the brain may cause this symptom. A tuberculoma of the brain should be thought of in this case.

Diabetes insipidus may cause frequency in urination. The urine in such cases is of low specific gravity.

The symptoms may be on a neurogenic basis or some other central condition. An eyeground examination and a careful neurologic examination would be of value in determining a central cause for the condition.

VITAMINS IN CHRONIC ALCOHOLISM

To the Editor:—Please outline the latest treatment for alcoholism for a patient on the verge of delirium tremens. I know there is almost complete avitaminosis in this condition and vitamin B₁, vitamin C and nicotinic acid are especially indicated. Please advise as to dosage and other measures.

M.D., North Dakota.

ANSWER:—Strictly speaking, vitamin therapy is not a treatment of alcoholism, but it frequently is of value in the treatment of the hypovitaminosis that accompanies chronic alcoholic addiction. This lack of vitamins is chiefly the result of the failure of addicts to eat sufficient vitamin-containing food. While the failure results in a lack of all of the food-contained vitamins, the most common clinical indication of vitamin lack is the occurrence of peripheral neuritis. This condition, formerly known as alcoholic neuritis, has been found to yield to therapy with thiamine hydrochloride (vitamin B₁). Hence the specific indication for thiamine is the occurrence of peripheral neuritis. This substance may be given in doses as high as 50 mg. daily and must be continued over a period of several weeks. Treatment may be begun with daily intravenous injection of from 20 to 50 mg. of thiamine hydrochloride. After two weeks, oral administration of thiamine may be employed with the same dosage, or the intravenous dose may be reduced. Treatment should be continued until the patient is relieved of the symptoms of neuritis.

Delirium tremens, another phase of alcoholism and usually precipitated by some injury or acute infection, does not respond well to thiamine hydrochloride. Another factor of the vitamin B complex, nicotinic acid, in many instances has been found to be effective here. Doses of from 0.3 to 0.5 Gm. are necessary. If a good response is obtained it will become evident in from twenty-four to forty-eight hours. While these doses are much larger than those usually employed when using nicotinic acid, unfavorable side effects have not been reported. The patient's skin may become flushed and he may describe a generalized feeling of warmth. It should not be necessary to continue the oral administration of from 0.3 to 0.5 Gm. daily for more than two or three days. The treatment of peripheral neuritis is a long range affair but that of delirium tremens is an acute emergency.

CIRCULATION AFTER CUTTING VEIN

To the Editor:—In an operation, blood vessels are cut and the closed circuit of the cardiovascular system ceases to be a closed circuit so far as the cut vessels are concerned. At the time of the cutting, the cut veins contain blood. A portion of this blood flows back into the wound. What happens to the blood that remains in the cut veins? The cardiac contractions can no longer supply to them pressure from behind, and many of them are so situated that adequate help from pressure occasionally exerted by externally placed skeletal muscles is out of the question. How does the blood remaining in the cut veins get back to the heart?

Edward E. Cornwall, M.D., Brooklyn.

ANSWER:—The presence of valves beyond the cut in the veins and the so-called venopressor mechanisms which create intermittent pressure on the remaining veins are sufficient to ensure that the blood remaining in the cut veins gets back to the heart. This applies, of course, to the veins between the cut and the heart. The venous blood flow is dependent not only on the residue of pressure remaining after the arterial blood passes through the arterioles, capillaries and venules but in addition is dependent to a large extent on the venopressor mechanisms, consisting (1) of the massaging action of skeletal muscles during their contraction and, to a lesser extent, during the tetanic twitching which constitutes muscle tone, (2) of the intermittent compressing action of the diaphragm during inspiration on the abdominal contents, including the blood in the veins, and (3) of the intermittent aspiration during inspiration created by the increase in negative intrathoracic pressure.

Gravity, depending on the position of the patient, would aid the venous return when the vessel is open.

Only a small portion of the cut vein will be separated from the closed cardiovascular circuit, since veins have a rich system of collaterals. The cut vein will empty its contents by a reflex tonic contraction of its musculature, and eventually the part distal to the venous valve will become fibrosed.

BOILS AND CARBOHYDRATE METABOLISM

To the Editor:—What is the present view of the role of a high carbohydrate diet in the etiology of recurrent boils? Is there any evidence to indicate that a change of diet in any way predisposes to this condition so long as it is adequate in respect to all essential food factors? Could you suggest any references?

J. G. Sheps, M.D., Eriksdale, Man.

ANSWER:—Osler, in the 1898 edition of his textbook (Osler, William: Practice of Medicine, ed. 3, p. 425) mentions boils and carbuncles as extremely common in diabetes. The skin is dry and harsh, sweats rarely, except in an occasional case in which drenching sweats alternate with polyuria. Eczema occurs and at times an intolerable itching, especially located on the genitalia. This was the picture of diabetic skin in the pre-insulin period. Not only the loss of resistance due to the general reduction of health by the metabolic disturbance but, added to this, the dry skin and intense itching predisposed to infection of the hair follicles, which resulted in boils and carbuncles. This has led to an idea quite general in the medical mind that all patients with boils have a defective sugar metabolism and that the dietary carbohydrates must be cut down to a minimum in order to aid recovery.

Tauber in 1933 came out in opposition to this idea and backed up his criticism of it by statistics (Tauber, E. B.: Hyperglycemia in Diseases of the Skin, *Arch. Dermat. & Syph.* 27:198 [Feb.] 1933). In his series of 514 diabetic patients only eighteen had furuncles, which good result he ascribes to the present day successful management of the disease. In 217 cases of cutaneous disease, including "seborrheic eczema, furunculosis and other pyodermias, dermatitis venenata, scabies, lupus, tinea and burns," he found no disorder of carbohydrate metabolism, blood sugar determinations ranging from 82 to 96 mg. per hundred cubic centimeters.

To test the matter further, he treated 189 cases of furunculosis by local applications of physiologic solution of sodium

chloride or weak solution of aluminum acetate and gave the patients a diet high in carbohydrates (Wenckebach No. 3) plus feedings of liver extract. In addition to this he gave daily injections of 5 per cent dextrose solution, 500 cc. intravenously. The feeling of pain and tension subsided in most cases after the second injection and the signs of inflammation diminished. In half the cases, the boil slowly absorbed without suppuration or sloughing. In only four of the 189 cases did a second boil appear, and in only one case was there a third one.

This experience seems to demonstrate not only that hyperglycemia is not a common accompaniment of furunculosis but that in many cases of furunculosis in which hyperglycemia has been ruled out recovery is aided by a diet high in carbohydrates and the intravenous injection of dextrose solution.

A dietary deficiency producing cutaneous changes such as the dryness of the skin in vitamin A deficiency can be expected to reduce resistance and predispose to follicular infection; but there is no reason to think that any diet "adequate in respect to all essential food factors" could so predispose unless there were some underlying disorder such as a disturbance of sugar metabolism. The careful search for such disturbance continues to be a prime requisite in the investigation of every case of furunculosis.

ANIMAL PARASITES AND MAN—CHLORINATION OF WATER

To the Editor:—1. Tenants in my seashore cottage last summer had dogs heavily infested with tapeworms and probably other things. The floors are of pine boards with wide interspaces to collect dust. It seems impossible really clean the house. Is there danger of infection, human or canine, from ova after the winter? 2. Our town water supply has been contaminated for years by herds of cows and flocks of sheep grazing about the pond and wading in the water to drink. My repeated complaints have been without effect on the local health officers and the state Department of Health at Providence disclaims jurisdiction. The water is heavily chlorinated. Will chlorination destroy the ova of animal parasites? Is not heavy chlorination of drinking water over years injurious to human beings? We have a record of a very high incidence of "appendicitis" and other gastrointestinal complaints among the native population, and many members of the summer colony, like myself, are forced to buy spring water for drinking and even cooking purposes.

M.D., Rhode Island.

ANSWER.—1. The only animal parasite of importance that may be acquired from dog feces is *Echinococcus granulosus* (hydatid cyst); the dog is infected via the ingestion of the raw flesh of infected sheep. The chance of infection with *Dipylidium caninum* is slight; only about 100 human cases have been reported.

2. (a) Chlorination does not destroy the ova of animal parasites.

(b) It is as yet open to question whether the ingestion of heavily chlorinated water over a long period of time is injurious to man. To date there is no direct and indubitable evidence of a harmful effect.

(c) The ingestion of materials heavily contaminated with bacteria not infrequently gives rise to gastrointestinal disturbances even though the bacteria are relatively nonpathogenic per se (as the colon bacillus) or killed by some pasteurization or sterilization process.

HIGH PULSE PRESSURE IN YOUNG ATHLETE

To the Editor:—What is the significance of a systolic blood pressure of 142 and a diastolic of 40 in an athlete aged 21? He is a boxer and in otherwise splendid condition. The Wassermann reaction is negative. Repeated blood pressure recordings have been made.

Stanley M. Gates, M.D., Monticello, Ark.

ANSWER.—Habitual exertion, such as occurs in physical training, frequently results in a gradual fall of the diastolic tension (Scott, V. T.: *Effects of Daily Exercise on Pulse and Arterial Pressure*, *Mil. Surgeon* 55:334 [Sept.] 1924). Violent exertion, such as occurs in boxing or running, increases the systolic tension and may result in some left ventricular hypertrophy. A systolic tension of 142 in a man aged 21 is, however, distinctly abnormal. One would wish to know more of the family history and past illnesses, particularly those in which occult renal injury may have occurred. Though the heart is obviously compensated at present, this does not preclude the possibility of organic defect. Thorough investigation by a 2 meter x-ray film, electrocardiogram and auscultation before, during and after exertion are urgently indicated. Aortic regurgitation is not an impossibility to account for the excessive pulse pressure. Such valvular lesions are occasionally discovered in athletes in otherwise excellent physical condition and with exceptional stamina and reserve for violent effort (Jokl, Ernst, and Suzman, M. M.: *Aortic Regurgitation and Mitral Stenosis in a Marathon Runner*, *The Journal*, Feb. 10, 1940, p. 467).

It is most important to know whether the diastolic tension was read at the fifth phase of silence or at the muffling of tone, the fourth phase. If the point of onset of the fifth phase was used, the error may be considerable: from 5 to 55 mm. (Melvin and Murray, *Quart. J. Exper. Physiol.* 45:1891, 1924). In certain pathologic states the fourth phase may be greatly prolonged and the beginning missed. As a source of error this possibility must be given due consideration.

Though a reading of 142/40 is unusual at any age, and particularly exceptional in young, presumably healthy, individuals, further study of the case should reveal an explanation. It is impossible to do more than suggest possible causes for these phenomena on the basis of the data submitted.

PREPARING FUNGUS EXTRACTS

To the Editor:—I would greatly appreciate any advice given for preparing extracts of cultures of skin fungus for subcutaneous injection.

L. F. Friedmann, M.D., Belize, British Honduras.

ANSWER.—Extracts of fungi can be prepared by two general methods. One commonly used for nonpathogenic fungi and also applicable to pathogenic fungi is as follows: The fungus is usually inoculated on a liquid medium such as Sabouraud's and allowed to grow at room temperature until sufficient maturity has been reached as judged by the production of a typical color or by the cessation of the growth. This usually takes from about ten days to three weeks. At the end of this period the fluid is drained off and discarded and the pellicle is killed by immersion in 95 per cent alcohol for from twenty-four to forty-eight hours. The pellicle is then dried and ready for extraction. The moist pellicle, prior to killing with alcohol, can be also extracted. The extracting fluid usually employed is a glycerosaline solution containing 50 per cent glycerin. After about twenty-four hours' extraction the material is filtered and the fluid sterilized by Seitz filtration. After routine testing for sterility, the material is ready for use when properly diluted.

Pathogenic fungus extracts are also commonly prepared by extracting the organisms with the medium in which they are grown, filtering the latter and using the fluid as the extract.

SEROLOGICALLY POSITIVE BLOOD SQUIRTED INTO EYE

To the Editor:—A physician treated a subungual hematoma by incision and digital compression, which compression caused some blood to squirt and enter his left eye. This accident occurred almost a month ago and immediately after the accident he treated his left eye with 20 per cent solution of mild protein silver. He took a blood specimen of his patient, which showed positive Kline and doubtful Kahn reactions. I started treatment with nearsphenamine immediately and have given him five injections thus far. I have also treated his eye with 1 per cent yellow oxide of mercury ointment. Since the accident occurred three weeks ago, I have not been able to discern any clinical evidence of infection or any primary lesion of the sclera, cornea or conjunctiva of the eye. Ophthalmoscopic examination has revealed no pathologic changes in the eye-grounds to date. Since there are no other clinical evidences of the presence of syphilis, I am planning to give him a series of only ten nearsphenamine injections. Will it be safe to say that there is no infection if no clinical evidence appears sixty days after the accident? Do you suggest that I start a series of bismuth injections after completing the arsenicals?

M.D., Ohio.

ANSWER.—The chances are that the physician-patient would not have contracted an infection from the small amount of blood which squirted into his left eye. As the patient has been already started on therapy, it puts both physician and patient in somewhat of a dilemma. It is similar to the man who has a suspected lesion on the penis and on whom treatment is started at once without the making of a positive diagnosis of syphilis. There is no such thing as half way measures for the treatment of syphilis. One either treats the patient fully or waits and keeps him under observation until a positive diagnosis can be made. Under the circumstances there seems to be no other course but continue the treatment just as if he had contracted syphilis.

The injections of nearsphenamine should be continued until a total of ten have been given. The first injection of bismuth subsalicylate should be given with the last of nearsphenamine and continued for a course of six injections, followed with another series of ten injections of nearsphenamine, and this in turn with eight further injections of bismuth subsalicylate, ending with a short course of eight injections of nearsphenamine and a final ten injections of bismuth subsalicylate. It is recommended that thereafter the patient be kept under observation, a serologic blood test being taken once in three months for the first year and twice a year thereafter. It is also suggested that a serologic blood test be taken at the end of each course of treatment.

PSORIASIS AND DIAGNOSIS OF SYPHILIS

To the Editor:—A young man has a rash over his body that resembles psoriasis, and a pathologist reports psoriasis from a biopsy. From twelve Wassermann reports he has had four positive and the rest negative. He has received some antisyphilitic treatment from various physicians at different intervals for the last ten months, at one time receiving treatment continuously for a period of twenty weeks, at which time he received ten injections of nearsphenamine and ten of bismuth in oil. During and following this treatment the lesions were no better. He has been to various good dermatologists, who all tell him after the original examination that he does not have syphilis. At a later date they get a positive Wassermann reaction and even though they have several negative Wassermann reactions they tell him that he has syphilis. The patient is married and has two children, aged 2 and 4 years, both well and with a negative Wassermann reaction. His wife is also well and has had six negative Wassermann reactions over the past eight months. I know that in certain conditions the Wassermann report is positive. Is psoriasis one of these conditions and in about what percentage of the cases does this appear? Am I justified in giving him antisyphilitic treatment with this history? How can I definitely prove to him that he does or does not have syphilis?

M.D., Alabama.

ANSWER:—Psoriasis is not among the conditions that tend to produce nonspecific or false positive "Wassermann" reactions. Of course, it is possible that a patient may coincidentally have psoriasis and syphilis, and likewise an occasional patient is seen who manifests a recurrence or relapse of the syphilis in the form of psoriasis-like plaques at the common sites for psoriasis, namely the extensor surfaces. The other diagnostic possibility offered by this patient is that he has psoriasis and is producing false positive serologic tests from some other cause.

The four positive and eight negative serologic reactions in the absence of clinical signs and no history of syphilis are not sufficient grounds on which to start treatment. The spinal fluid should be examined and, if found to be positive, the diagnosis of syphilis is then tenable. If the cerebrospinal fluid is negative, a specimen of blood should then be drawn, divided into four parts and one part sent to each of four laboratories. The reports from these combined tests might then be the basis for the decision with regard to the subsequent course for this patient. If the reports are in the main negative or if one or two of them are weak positives, the patient should be placed on observation and have serologic rechecks and a reexamination every six months for several years. On the other hand, if the majority of the reports are conclusively positive, this should be a sufficient ground for the diagnosis of syphilis and the institution of treatment.

It is not always possible to prove definitely to a patient that he does or does not have syphilis. Time with repeated serologic tests and reexaminations is often necessary to establish the diagnosis or prove the absence of the disease.

HEPARIN AND EMBOLISM

To the Editor:—A woman aged 42 has had rheumatic valvular heart disease for more than twenty years. There have been four episodes of right cerebral embolism in the last five years, the last attack occurring today. The origin of these emboli is evidently a mural thrombus in the left auricle. Has heparin been used in the treatment of such a case? The blood pressure ranges around 129/90. The pulse rate remains about 80 with a digitalis dosage of 25 minims (1.5 cc.) of the tincture each morning.

W. A. W. Switzer, M.D., Ridgway, Pa.

ANSWER:—It is possible that heparin may have been used in the attempt to prevent mural thrombosis in the auricles of a rheumatic heart in the absence of any active process in the way of acute rheumatism or bacterial endocarditis, but there has been little or nothing written of such an experience if it has been tried. It is hardly a practical measure, since the heparin must be given intravenously and would have to be administered repeatedly or for long periods in such a case as the one cited, in which there were evidently a good many months between embolic accidents. Thus, such treatment would be a different and even more difficult matter than that in coronary thrombosis and bacterial endocarditis, in which conditions experimental therapy has not yet yielded the adequately favorable results that were at first hoped for.

FRACTURE OF THYROID CARTILAGE

To the Editor:—I should like information with regard to the frequency with which fracture of the thyroid cartilage either on one or both sides occurs in accidental injuries. I should also like to know what the prognosis is with regard to complete healing of these fractures.

M.D., Arizona.

ANSWER:—L. A. Stimson (Fractures and Dislocations, Philadelphia, Lea & Febiger, 1912, p. 189) was able to collect twenty-four cases of fracture of the thyroid alone and published reports in the literature. Among these there were eighteen deaths and six recoveries. There were five cases of fracture of the thyroid cartilage and hyoid bone with three

deaths and two recoveries. There were nine cases of fracture of the thyroid cartilage and the cricoid cartilage, all fatal. There were two cases of fracture of the thyroid cartilage, cricoid cartilage and hyoid bone, with death. There were also two fatal cases of fracture of the thyroid cartilage, cricoid cartilage and trachea. Further details of these series are given by William Hunt (Fractures of the Larynx and Ruptures of the Trachea, *Ann. J. M.* 51:378 [April] 1866) and Albert Hénocque (Traumatic Fractures of the Larynx, *Gaz. hebdomadaire* 5:610 [Sept. 26], 625 [Oct. 2] 1868).

As Kellogg Speed (Fractures and Dislocations, Philadelphia, Lea & Febiger, 1928) said, prognosis is grave. "Primary death followed from suffocation after increasing dyspnea, emphysema or edema of the glottis." Tracheotomy is practically always indicated. The prognosis with regard to complete healing is doubtful. It may be necessary to wear a tracheotomy tube permanently.

IMMUNOTRANSFUSIONS IN LEUKEMIA

To the Editor:—A patient has recently told me of a reported immunotransfusion treatment for leukemia. His story is that a mother, given the blood from a child having leukemia, later gave life-saving transfusions to the same child. The mother also was used as a source of transfusions to cure leukemia in other patients subsequently. Is there any basis for this report?

M.D., Idaho.

ANSWER:—There is no good evidence that immunotransfusions of the sort described are of any value in leukemia in man. In certain kinds of transmissible leukemia of animals such effects have been described. But this condition, although superficially similar, is apparently an entirely different disease from that occurring in man. Transfusions of any normal blood may be of considerable temporary benefit in leukemia.

VESICOPERINEAL FISTULA AFTER RESECTION FOR CANCER

To the Editor:—What are the chances for a vesicoperineal fistula closing spontaneously? What, if anything, can be done if closure does not occur? This followed an abdominoperineal resection of a rectal carcinoma that was adherent to the bladder in the region of the trigon.

M.D., New York.

ANSWER:—In view of the fact that this patient had a resection for a cancer of the rectum that was adherent to the bladder, suspicions are naturally aroused concerning the possibility of recurrence, which may be a factor in the persistence of the vesicoperineal fistula. Therefore the first thing to do is to make a careful cystoscopic examination to determine whether or not the patient has cancer of the bladder. In addition the patient should have a careful examination in order to determine whether the cancer of the rectum has recurred. Naturally if the patient has had recurrence in loco and if he has cancer of the bladder, the cause of the fistula is self evident. If these two possibilities can be excluded, one might try to close the fistulous tract. A simple procedure that might be employed is one that is used in suprapubic fistulas, namely the use of a fulguration electrode. The fulguration may be repeated once or twice, but not oftener than once in four weeks. If the fulguration treatment fails to relieve the patient and if there are no signs of cancer, it might be well to discuss the advisability of operating on the patient. The nature of the operation will depend somewhat on what is found. If possible an attempt should be made to mobilize the bladder and close it by suture.

RHEUMATOID ARTHRITIS OR TUBERCULOSIS

To the Editor:—A man with a severe case of rheumatoid arthritis has a normal sedimentation rate. For one year I gave him autogenous vaccine, which seemed to improve his condition up to a certain point. This was followed by intravenous sulfur treatment, which apparently gave no results. Next I tried massive doses of vitamin D, which gave no results. Then I gave weekly doses of sodium iodide solution. Shortly after I began these treatments large fluctuating masses arose on the back of both wrists. These I considered to be panniculitis. On opening one of these masses I obtained a sterile serum and numerous little egg-shaped masses of fat. Would you consider this panniculitis and, if so, what do you consider the best treatment for it? Anything you may be able to advise me in the line of treatment for this patient will be greatly appreciated.

L. Jackson Lanich, M.D., Cumberland, Md.

ANSWER:—Severe rheumatoid arthritis with a normal sedimentation rate is most unusual, although it may occur. A more detailed clinical record would enable one to state with more certainty whether or not this diagnosis is correct, and therefore one would be in a much better position to advise as to further therapy. It is not surprising to learn that the patient did not respond to treatment with autogenous vaccine, intravenous sulfur or massive doses of vitamin D. This is the usual experi-

ence with these forms of therapy. The large fluctuating masses which finally appeared on the dorsum of the wrists were probably due to an associated tenosynovitis. The nature of the material aspirated is consistent with fluid obtained in some cases of rheumatoid arthritis. The small bodies may have been the rice bodies of tuberculosis. In order to be absolutely certain, one might reaspirate and inject some of the fluid into a guinea pig and thereby rule out tuberculosis. If they are not tuberculous in nature, conservative treatment is indicated.

AIRPLANE FLIGHTS AND DEAFNESS—OTOSCLEROSIS

To the Editor:—From time to time cases have been reported in which deafness has been relieved by an airplane flight. I am writing to inquire as to the rational explanation. 1. What type of deafness is relieved by this procedure? 2. If the barometric pressure is a factor, just how does it operate? 3. Is relief obtained through ascent or descent in the airplane? 4. Are surgical measures such as endaural fenestration to be generally recommended for middle ear deafness? I would appreciate any additional information or references with which you might supply me in regard to the treatment and prognosis in cases of otosclerosis.

M.D., Tennessee.

ANSWER.—1. Presumably deafness due to obstructions of the eustachian tubes.

2 and 3. By increasing air pressure on descent, air could be forced into closed eustachian tubes or the rarefied air on ascent could allow air under greater pressure in middle ears to escape through the eustachian tubes. The former would be comparable to performing the Valsalva experiment; the latter is comparable to the creating of artificially lowered pressure into the nasal chamber by forcibly drawing air into the nostrils.

4. Only when the ears are dry, the nerve function and general physical condition good and the patient prefers a surgical operation to wearing a modern electrical hearing aid.

In cases of otosclerosis the prognosis is bad. The treatment can be satisfactorily outlined only by a competent otologist, under whose direction the patient should place himself. The use of an electrical hearing aid and lip reading are recommended.

BRADYCARDIA IN JAUNDICE

To the Editor:—I should like to know the explanation for the bradycardia present in clinical jaundice.

M.D., Michigan.

ANSWER.—Bradycardia as a result of jaundice has been observed for many years but there is still no clearcut explanation for it. Many theories have been advanced and later rejected. At the present time the most widely accepted explanation predicates the bradycardia resulting from vagal stimulation due to the presence of bile salts in the blood. This explanation has some experimental backing. Injection of bile salts into the blood of young dogs will produce bradycardia but a similar effect is often lacking in older animals. Another hypothesis has to do with the combination of bile salts with calcium, thus reducing the irritability of the heart muscle.

Neither of these nor any other theory has been definitely proved.

CHOICE OF MATERIAL IN ARTIFICIAL LIMB

To the Editor:—In supplying a patient (an adult aged 21) with an artificial leg, is one made of wood or one made of airplane metal or of so-called fiber preferred?

M.D., Connecticut.

ANSWER.—Surgeons who have had wide experience in the fitting of artificial limbs do not agree in all instances with regard to the choice of materials for the manufacture of such legs. Needless to say, manufacturers of each of the three types of limbs mentioned can supply rather impressive arguments tending to show that the material which they may happen to use is the most desirable. A metal or fiber leg cannot be altered as easily as can a wooden leg. There is little difference in the weight when the leg is completed. If the patient works outdoors in varying temperatures the metal leg will become chilled much more quickly, as it is a better conductor than either the wooden or fiber limb. The socket for a metal or fiber leg is made; by stamping it out. If the model and the measurements are absolutely accurate from the beginning, this is of course quite satisfactory. On the other hand it is frequently necessary to make some slight alterations in order to provide a more perfect fitting, and changes cannot be made so easily in the case of the metal or the fiber leg. The argument has also been presented that the polished, more neatly and more quickly. It is believed that the artificial leg made of wood is to be preferred for the average patient.

SMALLPOX VACCINATION ON BACK

To the Editor:—Is it recognized as good routine practice to vaccinate babies for smallpox on the back? If so, in what region should the child be vaccinated? I would appreciate an early reply.

M.D., Wyoming.

ANSWER.—It is not recommended generally as good routine practice to vaccinate babies on the back for smallpox. When vaccination is done on the back, a site high up over the left scapula is sometimes chosen. Vaccinations in this locality are seen more often probably on European women than on women in this country. It seems likely that vaccinations on the shoulder posteriorly are no more objectionable than vaccinations on the leg. Ordinarily the area above the insertion of the left deltoid is given preference.

ANTIRABIC TREATMENT AND RAT BITE

To the Editor:—A 3 year old boy was bitten several times by a rat. He was taken to the hospital and under gas-oxygen anesthesia the wounds were cauterized carefully with fuming nitric acid. Would you advise vaccinating him against rabies?

M.D., Massachusetts.

ANSWER.—The rat, like other mammals, is susceptible to rabies. If the dictum "safety first" is to obtain in such cases as the one mentioned the patient would have to be given antirabic treatment.

SULFAPYRIDINE AND PNEUMONIA

To the Editor:—The answer to the question about sulfapyridine and prophylaxis of pneumonia (The Journal, April 27, p. 1689) should not pass unchallenged. While the first sentence of the reply is valid, it hardly seems wise, in the light of present knowledge, to state that the "signs and symptoms of an actual involvement of the bronchi and lungs" constitute an indication for treatment with sulfapyridine. It is not only "a good practice" but a rigid necessity to attempt to determine the cause of the infection before treating it. It is highly doubtful that "sulfapyridine now constitutes the sheet anchor in the treatment of acute infectious pulmonary disease." If the statement were limited to acute pulmonary disease caused by pneumococci or hemolytic streptococci it would be more in keeping with established facts. In my recent experience (Arch. Int. Med. 65:138 [Jan.] 1940) a form of pneumonia caused by an agent other than these bacteria was more prevalent than pneumococcal or streptococcal pneumonia. Sulfapyridine was found to be of no value in this type of infection and actually increased the discomfort of the patient. In certain cases, however, it is admittedly difficult to decide whether or not to use the drug. For example, if pneumococci of certain types (I, II, III, V, VII, VIII or XIV) are present in the sputum in cases of atypical pneumonia it may be difficult to decide whether they are actually causing pneumonia or are potential invaders. In such circumstances the drug should probably be given the benefit of the doubt and given the drug. Until further facts are known, the decision rests largely on accurate observations and good judgment. At any rate there is at present no justification whatever for the routine use of sulfapyridine for the prevention of pneumonia. In the same issue of The Journal, page 1605, mention of pneumonia. In the same issue of The Journal, page 1605, Brown, Thornton and Wilson state that "the range between adequate blood concentrations [of sulfapyridine] and those which carry an unwarrantable risk of serious toxicity has been shown to be so narrow as to provide justification for a more conservative approach to the chemical treatment of pneumonia and to constitute a valid argument against the indiscriminate substitution of sulfapyridine for sulfanilamide in nonpneumococcal infections."

Hobart A. Reimann, M.D., Philadelphia.

FRIGIDITY IN WOMEN

To the Editor:—Under the title "Frigidity in Women" in the May 11 issue of The Journal there is a criticism by Dr. A. L. Walbarst (p. 1952) of the answer to Dr. Dunn's inquiry on March 23, page 1100. Dr. Walbarst says: "The answer to Dr. Dunn's inquiry regarding frigidity in women fails to mention a form of frigidity which may be considered constitutional and perhaps hereditary." He then describes a case and says in the last paragraph: "At the examination it was found that there was no response whatever at the clitoris or in the vagina either to manual manipulation or the electric current. She was absolutely anesthetic in those regions." This condition is, however, fully described in the original answer (third paragraph) as follows: "There is another form of frigidity due to an organic condition in women, namely partial or complete sexual anesthesia in the vaginal mucous membrane. This condition has been described by Huhner (The Diagnosis and Treatment of Sexual Disorders in the Male and Female Including Sterility and Impotence, Philadelphia, F. A. Davis Company). One must have experience however in making this diagnosis, as different portions of the female genital tract have different degrees of sensitivity."

Max Huhner, M.D., New York.

"GATCH" BED

To the Editor:—With regard to the query on page 1579 of The Journal for April 20 as to the meaning of the term "gatch" in connection with hospital beds, there are two schools of thought on this subject. The response in The Journal is representative of one. The other is conditioned on an article by Dr. W. D. Gatch in the Annals of Surgery 49:410, 1909, with one illustration of the principle. The title of the article is "The Sitting Posture: Its Postoperative and Other Uses, with a Description of a Bed for Holding a Patient in This Position."

Ramsay Spillman, M.D., New York.

Medical Examinations and Licensure

COMING EXAMINATIONS NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, June 15, page 2407.

STATE AND TERRITORIAL BOARDS

ALASKA: Juneau, Sept. 3. Sec., Dr. W. W. Council, Box 561, Juneau.

ARIZONA: Phoenix, July 2-3. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

CALIFORNIA: Oral examination (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), Los Angeles, July 15. Written examination. Los Angeles, July 15-18. Sec., Dr. Charles B. Pinkham, 1020 N. St., Sacramento.

CONNECTICUT: Written, Hartford, July 9-10. Endorsement, Hartford, July 23. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. Homopathic, Derby, July 9-10. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: Examination, Dover, July 9-11. Reciprocity, Dover, July 16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: Basic Science, Washington, Oct. 21-22. Sec., Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Basic Science, Gainesville, Nov. 1. Applications must be on file not later than Sept. 16. Sec., Dr. John F. Conn, John B. Stetson University, De Land.

GEORGIA: Atlanta, June. Joint-Sec., Mr. R. C. Coleman, 111 State Dr. George C. Ruhland, 203 District Bldg., Washington.

IDAHOO: Boise, Oct. 1. Dir., Bureau of Occupational License, Mr. H. B. Whittlesey, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, June 25-27. Superintendent of Registration, Mr. Lucien A. File, Springfield.

IOWA: Basic Science, Des Moines, July 9. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

MAINE: Augusta, July 2-3. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

MASSACHUSETTS: Boston, July 9-11. Sec., Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: Basic Science, Detroit, June 28-29. Pres., Dr. R. C. Houston, East Lansing.

MISSISSIPPI: Jackson, June 26-27. Asst. Sec., Dr. R. N. Whitfield, Jackson.

Iowa March Report

Mr. H. W. Grefe, director, Division of Licensure and Registration, reports the written examination held at Des Moines, March 4-6, 1940. The examination covered eight subjects and included 100 questions. An average of 75 per cent was required to pass. Seven candidates were examined, five of whom passed and two failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Chicago College of Medicine and Surgery.....	(1917)		84.9
Rush Medical College.....	(1939)		85*
Tufts College Medical School.....	(1930)		85.3
Creighton University School of Medicine.....	(1938)		83.3
Medizinische Fakultät der Universität Wien.....	(1935)		88.9
School	FAILED	Year Grad.	Number Failed
Medizinische Fakultät der Universität Wien.....	(1935)		1
Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät, Bonn.....	(1920)		1

Twelve physicians were licensed by reciprocity and four physicians were licensed by endorsement from January 31 through March 18. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Arkansas School of Medicine.....	(1935)		Arkansas
Northwestern University Medical School.....	(1934)		Illinois
University of Kansas School of Medicine.....	(1938)		Kansas
University of Maryland School of Medicine and College of Physicians and Surgeons.....	(1924)		Maryland
University of Michigan Medical School.....	(1924), (1935)		Michigan
St. Louis University School of Medicine.....	(1922)		Missouri

Book Notices

Principles and Practice of Aviation Medicine. By Harry G. Armstrong, B.S., M.D., Capt., Medical Corps, United States Army. Cloth. Price, \$6.50. Pp. 496, with 86 illustrations. Baltimore: William Wood & Company, 1939.

Out of a tremendous personal experience and out of a review of more than 4,000 separate papers on the subject, Captain Harry G. Armstrong, of the Medical Corps of the United States Army and director of the Aero Medical Research Laboratory, has provided the medical profession with a textbook on the principles and practice of aviation medicine that constitutes an epoch in this field. Here is the one book which makes available to the physician advice necessary to examine pilots, to inform patients about flying and to take care of many of the illnesses and emergencies associated with modern aviation.

The book begins with an excellent statement on the history of aviation and on its medical aspects. Then comes a discussion of the flight surgeon and all the details involved in the selection of pilots, including references not only to the eye and the heart and to the ear, nose and throat, but also to the general physical examination and neuropsychic examination. A chapter on the care of the flier is followed by a discussion of fluids, gases, wind, ventilation, cold and other factors involved in flight, and of the effects of flight on the ear and on orientation. There is a discussion of air sickness and altitude sickness, of the effects of oxygen and atmospheric pressures, and then some highly technical discussions dealing with embolism and the effects of speed and acceleration. Some of the most interesting chapters for the general reader are the concluding discussions of the psychology of flight and of the new problems in sanitation raised by flight.

The book is well written and handsomely illustrated, and it has an excellent index.

Der Scharlach in Finnland bis einschliesslich 1900. Von Dr. Max Björkstén. Am. 16 November 1936 von Axel Wallgren und All Krogus vorgelegt. Acta Societatis scientiarum fennicae, Nova series B. Tom I, N: o 3. Paper. Pp. 264. Helsingfors: Akademische Buchhandlung; Berlin: R. Friedländer & Sohn, 1938.

This extensive statistical study of scarlet fever in Finland covers a period of 139 years, beginning with 1762 and ending with 1900. As the author states, the diagnosis of scarlet fever during all of the eighteenth and first part of the nineteenth century was uncertain and official statistics are scanty; nevertheless, contemporary reports of the more severe epidemics furnish reasonably reliable information. The first recorded epidemic of scarlet fever in Finland occurred in September 1755. It resulted in the death of many children from 6 months to 5 years of age on the third to the seventh day of illness. Though the disease was epidemic, it did not impress observers as contagious in the sense of being transmitted by direct contact. The year by year statistics as to incidence of scarlet fever and death rate due to this disease in Finland, which occupy 150 pages, are summarized and tabulated in subsequent chapters. The prevailing weather conditions compared with the incidence of scarlet fever showed no relationship other

than the well known seasonal variation resulting in a maximum number of scarlet fever cases in January, a decrease in the late spring and a slight rise in late summer, continuing into the sharp rise of fall. The chapter on treatment describes the symptomatic therapy which prevailed and how, since this appeared ineffective, the people lost confidence in the power of medicine to influence the course of scarlet fever and frequently did not send for a doctor when the disease appeared. Since the period covered by this report ends with the year 1900, scarlet fever antitoxin was not yet available. After citing opinions to the contrary, the author concludes that scarlet fever must be considered a contagious disease. The monograph will not interest clinicians but it constitutes a definite contribution to public health statistics.

The Medical Staff in the Hospital. By Thomas Ritchie Ponton, B.A., M.D. Cloth. Price, \$2.50. Pp. 288. Chicago: Physicians' Record Company, 1939.

This book is written by a physician who by training and experience is thoroughly qualified to discuss the various phases and problems of hospital administration. It is a comprehensive and authoritative treatise which presents the full range of material that concerns the medical staff in its relation to the hospital service. The author has furnished information of a most practical nature and has succeeded in crystallizing in a single volume the subjects that are essential to the study of staff organization as a whole. There are nine chapters describing in a logical and systematic manner the obligations of the governing board and the medical staff, the relation of physicians to hospital service, the selection and appointment of staff members, the principles of staff organization, by-laws, rules and regulations, staff meetings, medical records, professional accounting and classification, and administrative relationship of the resident medical staff. There are many valuable illustrations, a list of standard forms relating to staff organization and medical records, and an ample index of ten pages. Addenda are included concerning the American Medical Association's standards for intern training, the Essentials in a Hospital Approved for Residencies in Specialties, the requirements for approval of internships in Canada, the minimum standards of the American College of Surgeons, by-laws, rules and regulations for various types of hospitals, a schedule of standing orders and sample regulations applicable to the intern staff. In this volume the author has described clearly the interrelationship of the medical and administrative personnel and the obligations of the staff in assuming control of medical policies and professional services. His emphasis on the qualifications and responsibilities of the medical staff is of particular significance, since these factors are of paramount importance in the care and welfare of patients. Staff physicians, superintendents, record librarians and others interested in hospital administration will find this book a valuable source of information and reference.

Sbornik trudov. Tom V: K pyatidesyatiletiyu Tomskogo Gosudarstvennogo Meditsinskogo Instituta imeni V. M. Molotova, 1888-1938. [Collection of Works Celebrating 50th Anniversary of Tomsk Medical Institute (Named after V. M. Molotov). Volume V.] Cloth. Price, 9 rubles. Pp. 274, with illustrations. Tomsk: Izdatelstvo "Krasnoe Znamya," 1939.

This volume is a festschrift contributed to by the members of the Tomsk Institute of Physical Therapy and Balneology on the occasion of the fiftieth anniversary of the Tomsk Medical Institute. The subjects treated are those concerned with the effect of diathermy, iontophoresis and other physical therapeutic procedures in various disease states. The contribution by Shpisman on diathermy treatment of chronic disease of the heart is worthy of comment because of its conservative attitude. Among the contraindications to this treatment the author lists valvular diseases of the heart with decompensation, coronary thrombosis, dilatation of the aorta accompanied by hypertension, myocarditis accompanied by serious vascular alterations, exophthalmic goiter, the tendency to pulmonary hemorrhages, and very high or markedly lowered blood pressure. Diathermy is indicated in chronic disease of the heart characterized by painful sensations and mild myocardial lesions of a dystrophic type. The beneficial effect of the treatment manifests itself in the relief of pain and in the improvement of the cardiac function. Thirty-seven and eight-tenths per cent of the author's patients were completely relieved of the pain. In 51.5 per cent considerable diminution of the pain was registered. Subjective improve-

ment was noted in 89.5 per cent. Extrasystoles of functional character disappeared as a rule, whereas extrasystoles as a result of an organic cardiac lesion were not influenced. Tachycardias and bradycardias of cardiac origin not complicated by grave irreversible lesions become regulated as a rule.

Health in Relation to Occupation. By H. M. Vernon, M.A., M.D. Cloth. Price, \$4.50. Pp. 355, with 50 illustrations. New York & London: Oxford University Press, 1939.

Heredity affects health through the inheritance of good physique and intelligence. Under the heading of social environment, nutrition is by far the greatest single influence on physical welfare, exceeding by a considerable margin parental care, housing, sanitation and other elements which depend fundamentally on wages. Occupation affects health in a great many direct and indirect ways. In any event, it is a particularly difficult assignment to dissociate the effects of these three factors one from the other. Nevertheless, Vernon feels it worth while to set up certain percentage relationships between these factors, tentatively at least, until further observation by him and others may suggest abandonment or further exploration of this method of evaluation. These, in substance, are a few of the author's reflections on a most interesting subject, which, at least in this country, receives far less consideration in medical publications than it deserves. This book refers mainly to British conditions, although the general recommendations and conclusions have a much wider application. In fact, it is mainly in England that good statistical data are available for compilation and review concerning the effects of work and economic status on health. The occupational mortality data, for example, as published in the Registrar General's Decennial Supplements have no close counterpart in other countries. Nowhere are there accumulations of data on sickness and occupation except where the work itself has been discovered as the direct etiologic agent. Vernon concludes that "The greatest single factor for the improvement of the nation's health is the provision of an adequate income for all members of society." To this expression the great majority of physicians in this country can voice substantial agreement.

The Health of the Chinese in an American City, San Francisco. J. C. Gelger, M.D., Emmett E. Sappington, M.D., Roslyn C. Miller and Hilda F. Welke, A.B., San Francisco Department of Public Health. Paper. Pp. 29. San Francisco, 1939.

This interesting and instructive report opens with a brief contrast of conditions in the Chinese section of San Francisco in 1870 and the changes that have been made in this section of the city since that time. During the ten year period ended in 1938 there has been a noticeable decrease in the birth rate among the Chinese. Among the tangible results of the efforts in the education of Chinese mothers is the increase in the number of those who have been hospitalized at the time of delivery. In 1929 only 20 per cent of births occurred in hospitals, whereas in 1938 there were 56 per cent, an increase of 180 per cent of birth in hospitals. As a contrast, 82 per cent of citywide births in 1929 were in hospitals and 92 per cent in 1938, an increase of 12 per cent. One of the major health problems in the Chinese area is tuberculosis, which is associated with crowded housing conditions and long working hours leading to fatigue. The pulmonary type accounted for 67 per cent of all cases of tuberculosis; 78 per cent of patients were under 25 years of age; of the families in which tuberculosis was found, 60.7 per cent of the heads of families had an income of less than \$70. Over the ten year period 1929-1938 there has been a constant decline in the Chinese general death rates. Citywide death rates have never reached the approximated 18.1 Chinese rate per thousand of population in 1929 and they have never declined to the low Chinese rate of 9.83 for 1938. The average age at death for the city was 52.4 years and for the Chinese 41.7 years in 1929. In 1938 the citywide average age at death was 58.3 years and for the Chinese 50.8 years. These and other changes noted in the report are attributed largely to the development of public health measures among the Chinese; however, it appears that even greater advances might have been recorded were it not for evidence that the Chinese, especially the early age groups, have greater susceptibility and less resistance to disease. This report is an encouraging evidence of some of the accomplishments possible through public health education and properly sustained public health administrative measures.

Love at the Threshold: A Book on Dating, Romance and Marriage. By Frances Bruce Strain. Cloth. Price, \$2.25. Pp. 349. New York & London: D. Appleton-Century Company, Incorporated, 1939.

The physician seeking a book which he can recommend for reading by boys and girls and young men and women can place confidence in this volume. It is comprehensive, practical, sensible and scientific. It is written in a sympathetic style which indicates the author's genuine interest in and wide acquaintance with personal problems of young persons, especially those having to do with relationships between the sexes on three principal levels with which the book deals, namely, dating, romance and marriage. The only objection which some physicians may have to the book would seem to be its somewhat excessive confidence in the rhythm theories as contraceptive methods, perhaps a bit too much optimism on the ease and safety of modern motherhood. The book deals with its three principal topics adequately and without overdoing the preaching attitude. It is the kind of book which a young woman whose opportunities for acquiring poise and social graces have not been too abundant may read with assurance and which the girl during courtship and approaching marriage may find a valuable guide. It is perhaps less suitable for boys than for girls, but even so the adolescent boy will find useful information in it. Parents who are being asked questions which they cannot answer, or parents whose answers are not acceptable to their own offspring, may find welcome corroboration and cooperation in the advice contained in this book.

Suchasna metodika zashchitvego farbuynnya nerviv metilenovoyu sin-koyu i inshimi farbnikami. [By] O. V. Leontovich. [Present Day Methods of Vital Staining of Nerves with Methylene Blue and Other Stains.] Paper. Price, 3 krb. 50 kopceks. Pp. 88, with 4 illustrations. Kiev: Vydavnistvo Akademii Nauk URSR, 1939.

This is a monograph devoted to the discussion of the newer methods of supravital staining of nerve tissue. The silver methods of staining of Golgi and of Ramon y Cajal had a limited field according to the author. The Bielschowsky was an advance. It did not stain, however, all the neuroplasma, but only the primary nerve fibers. The pericellular elements were poorly stained and the neuroplasma of the nerve fibers barely demonstrated. The greater part of the monograph is devoted to the discussion of the newer methods of fixation and of supravital stains with methylene blue developed in the recent years in the Union of Soviet Socialist Republics. The work of the School of Vorobiev is discussed in considerable detail. The method enables the demonstration of the nervous system in its finest divisions. The newer methods of fixation permit preparations to be examined with the oil immersion lens. Sections of the thickness of from 0.25 to 0.5 mm. enable one to study innervation as it is rather than in reconstruction pictures. A fairly exhaustive biography on the subject is appended. The book is written in the Ukrainian and, contrary to the usual custom, does not contain a summary in any other language.

Hospital for the Ruptured and Crippled: A Historical Sketch Written on the Occasion of the Seventy-Fifth Anniversary of the Hospital. By Fenwick Beckman, M.D. With a foreword by Philip D. Wilson, M.D., Surgeon-in-Chief. Cloth. Price, \$3. Pp. 157, with 11 illustrations. New York, 1939.

As has often been stated, prior to 1863 philanthropists, public officials and the people as a whole did not show any real recognition of a social responsibility for those who were physically maimed. Throughout the United States not one single hospital specifically dedicated to the care of the crippled could be found. In that year, while the Civil War with all its horror was creating countless thousands of crippled individuals, the Hospital for Ruptured and Crippled was founded. This book consists of a fascinating history of the first seventy-five years of that institution. To some extent this record shows the influence which the Hospital for Ruptured and Crippled exerted throughout the United States on medical and surgical thought and the care of physically disabled individuals, from both the technical and the social point of view. Begun in the home of Dr. James Knight, with a small group of patients, this institution has provided for more than 800,000 individual men, women or children the benefits of care which could be rendered only by a skilled staff of doctors who were dedicating their lives to this special work. Many advances in orthopedic technic have had their origin within the walls of

this institution. In every section of the country may be found orthopedic surgeons who received their training as assistants to the staff of surgeons of the Hospital for Ruptured and Crippled. The volume contains many personal references and constitutes a record of achievements of many professional and lay individuals who worked faithfully that this institution might survive and fulfil its appointed function.

The Tools of the Chemist: Their Ancestry and American Evolution. By Ernest Child. Cloth. Price, \$3.50. Pp. 220, with 105 illustrations. New York: Reinhold Publishing Corporation, 1940.

This volume is a fascinating work which might well be duplicated in the field of medicine. It provides biographic data as well as the history of apparatus and materials used in the chemical profession. Here is the ancestry and development of balances, glassware, filter paper, rubberware and optical apparatus used by chemists. There are innumerable excellent illustrations in the forms of photographs, drawings and portraits.

Modern Marriage. Edited by Moses Jung. Cloth. Price, \$3.75. Pp. 420, with 37 illustrations. New York: F. S. Crofts & Co., 1940.

For the last six years the State University of Iowa has offered a course on modern marriage in which members of the entire faculty have participated. The course has been coeducational and has included both married and unmarried students. The discussions in the course have been exceedingly frank. In this volume the aspect of mental hygiene is discussed by John M. Dorsey of the University of Michigan, the biologic aspects by Dr. Andrew H. Woods of the department of psychiatry, the physical aspects by Dr. E. D. Plass of the department of obstetrics. The volume discusses as well legal aspects, economics, religion, art and intelligence. There is some discussion of contraception and premarital examinations. The book should prove not only interesting but extremely valuable to any intelligent adult who contemplates marriage. It should also be especially suggestive to physicians and teachers who may be charged with the duty of advice for those who do not wish to avail themselves of a volume of this type.

Men Against Madness. By Lowell S. Selling, M.D., Ph.D. Cloth. Price, \$3.50. Pp. 342, with 42 illustrations. New York: Greenberg, Publisher, 1940.

By a series of biographies and historical anecdotes Dr. Lowell Selling traces the development of our modern methods of treating diseases of the mind. It becomes quickly apparent that physicians recognized from the first the intimate relationship of mind and body, although there were innumerable tendencies toward separating the consideration of their disturbances. As long as human beings believe in magic, it was certain that mental conditions would be treated from the point of view of the magician. Then came Pinel, who struck the chains from the insane. Scientific progress was also inhibited to some extent by the charlatans, although these charlatans themselves did help to advance study of the mind. Prominent, of course, are Gall, who founded phrenology, and Mesmer, who developed animal magnetism. Coincidentally came the great discoveries of the scientists who dealt with the structure and function of tissues, psychologists and psychiatrists. The modern era culminates, of course, with the evolution from Charcot to Freud. From the time of Kraepelin and Freud psychiatry has advanced tremendously. The physician and the layman who wish to orient themselves in this field can do so pleasantly with this well written volume by Dr. Selling.

High Schools and Sex Education. By Benjamin C. Gruenberg, Special Consultant to U. S. Public Health Service. With the assistance of J. L. Kaukonen. United States Public Health Service, Federal Security Agency. Bulletin No. 75 revised. Paper. Price, 20 cents. Pp. 110. Washington, D. C.; Supt. of Doc., Government Printing Office, 1939.

This pamphlet is published by the United States Public Health Service to set forth a point of view with relation to how sex education had best be carried out. Acknowledging the necessity for primary sex teaching in the home and deploring the general lack of such teaching, the booklet postulates the theory that the school must do what the home fails to do. In the presence of such a Hobson's choice, the proposal set forth in the booklet should meet with general approval. The booklet is divided into three principal parts, exclusive of the foreword and introduction. Part one has to do with planning and organization in

the secondary schools, containing chapters on the province of the school, methods and supplementary devices, and teacher selection, preparation and development. Part two indicates how sex instruction can be integrated with various courses, including biology, general science, physiology and hygiene, physical education, home economics, social studies and English. There are four appendixes containing respectively a reading list for teachers and school officials, a reading list for students, information on pamphlets and visual aids, and a suggested outline of a course for teachers on sex education in secondary schools. The manual is a comprehensive and thoughtful presentation and should be useful for reference in any situation in which the problem of sex education in the schools is under consideration.

The Becoming of Oswald or Wake Up and Loaf. By Emmanuel Winters. Cloth. Price, \$1.50. Pp. 144. New York: Milestone Press, 1939.

This little satire purports to give a picture of the American with a superiority complex or what the author believes is a typical American. Oswald begins by being as timorous as Mr. Webster's "Gentle Soul" but he soon discovers that it is possible by reading Elbert Hubbard's Scrapbook and similar works to become a success. Oswald becomes successively a New Yorker, an architect, a doctor—that is to say, one of those laymen who are ready to prescribe for every one's illnesses—a materialist, a financier, a coin collector, a prophet and a revolutionary. Finally he becomes a real success by winning a \$50,000 prize in the Irish Sweepstakes.

MEDICOLEGAL ABSTRACTS

Accident Insurance: Death from Typhoid Is Death Resulting from "Disease in Any Form."—The defendant company issued a policy of insurance providing stated benefits if the insured died "as a result, directly and independently of all other causes, of bodily injuries, effected solely through external, violent and accidental means, of which . . . there is a visible contusion or wound on the exterior of the body . . ." Under the policy no benefits were payable if death resulted directly or indirectly from "disease in any form." The insured contracted typhoid from drinking contaminated water and died. His beneficiary brought suit under the policy. A judgment of the trial court in favor of the insurance company was reversed by the Kansas City (Mo.) court of appeals and the company appealed to the Supreme Court of Missouri.

The death of the insured, contended the beneficiary, was clearly within the terms of the policy because the ingestion of the typhoid germs by the insured was accidental, the bacteria were external means producing violent injuries resulting in death, and the visible contusion or wound on the exterior of the insured's body required by the policy was present in cracked and "blackened" lips, which appeared after the inception of the disease and before death. The provision of the policy, it was further contended, excluding death from disease should be construed not to apply in this case because the disease followed or was incidental to accidental bodily injuries caused by the germs. But, said the Supreme Court, the terms of a contract of insurance must be taken in their plain, ordinary and popular sense. Under such a rule of construction the Supreme Court held that the beneficiary could not recover under the policy because of the provision denying liability if death resulted from "disease in any form." This provision is clear and unambiguous and cannot be construed to warrant a finding that typhoid is not a disease. The court was not impressed with the beneficiary's contention that the ingestion of the bacteria caused an injury which in turn resulted in the disease and that therefore death was due to injury and not to disease and so was not within the exclusion clause. Common understanding, said the court, forces the conclusion that typhoid, the disease, was the proximate cause of death. Any bodily injury suffered by the insured was an incident of the disease.

To uphold the beneficiary's contention would be to decree that all death from disease would be covered by the policy because a normal person would not intentionally expose himself to bacteria which causes disease and so the contracting of disease would always be accidental. There would then be no difference between an accident and a health insurance policy. However, the ordinary man draws a clear distinction between bodily injury and disease. The court concluded, therefore, that because of the exclusion clause here discussed the policy did not cover death resulting from typhoid, which is a disease not brought about by accidental bodily injuries.

Accordingly, the judgment of the appellate court was reversed and, in effect, judgment was rendered in favor of the insurance company.—*State ex rel. Prudential Ins. Co. of America v. Shain (Mo.)*, 127 S. W. (2d) 675.

Malpractice: Gas Gangrene Following Injury to Hand.—The plaintiff injured his left hand while cutting brush. He engaged the defendant physician to treat him, but after a few treatments he employed other physicians to attend him instead. The latter physicians extracted from his hand two or three splinters, incised the hand in several places and inserted gauze drains. Within two or three days after they commenced to treat the plaintiff they discovered that the wound had become infected. They diagnosed the condition as gas gangrene and thereupon amputated the patient's left hand and arm at a point above the elbow. Subsequently the patient sued the defendant physician for malpractice. From a judgment in favor of the plaintiff the physician appealed to the court of civil appeals of Texas, San Antonio.

The burden rested on the plaintiff, said the court of civil appeals, to prove that negligence on the part of the defendant in his treatment of the patient was the proximate cause of the infection which necessitated the amputation of his "hand." In the judgment of the court, the plaintiff had failed to do so. The evidence adduced showed that the defendant examined the plaintiff's hand under a fluoroscope to detect any possible fracture, probed the wound and extracted therefrom a splinter, washed the wound with an antiseptic and approximated the edges of the wound with "a clamp." It was not shown that the infection which necessitated the amputation was in any way caused by negligence on the part of the defendant. One of the medical witnesses for the plaintiff, in answer to a hypothetical question, did testify that the treatment rendered was negligent but on cross examination he admitted that he would have used the same treatment as the defendant had used. All the experts testified that the infection could have occurred regardless of the treatment administered to the wound. The fact that the wound became infected could not be said to be evidence of want of care on the part of the defendant in his treatment of the injury. Since the court was of the opinion that the cause of the infection in this case was known only to those trained in medical science, it concluded that the trial court had erred in overruling the defendant's motion for a directed verdict in his favor and in submitting the cause to the jury.

Accordingly, the judgment of the trial court in favor of the plaintiff was reversed and the cause remanded for a new trial.—*Kootsey v. Lewis (Texas)*, 126 S. W. (2d) 512.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Cardiac Changes in Pregnancy Unrelated to Heart Disease.—Sodeman observed seventy-three apparently normal patients during pregnancy to ascertain what cardiac changes resulted from the gravid state. Palpitation or dyspnea or both developed in thirty-one and was sufficiently severe to constitute a complaint. Choking or "smothering" at night was complained of by two. Soft systolic murmurs were common and, at times, were markedly affected by posture. In thirty instances, soft, short, transient, systolic pulmonic murmurs were heard. Of the more constant systolic murmurs, eighteen were both apical and basal, six were apical alone and eight were basal alone. A diastolic murmur was heard at the aortic area in one case. Gallop rhythm occurred eight times, and a definite accentuation of the pulmonic second sound thirty-one times. Accentuation of the aortic second sound occurred twice and splitting of the mitral first sound five times. The heart was definitely beyond the midclavicular line in twelve cases, confirmed by x-ray examination in ten. Tachycardia was recorded graphically in forty-seven cases and ectopic beats in four. Edema of the ankles was present in twenty-eight. The blood pressure of every patient remained within the normal range. In seven of the seventy-three patients symptoms and signs sufficient to suggest heart disease developed in the last trimester. In five of these, palpitation and dyspnea on exertion were accompanied by accentuation of the pulmonic second sound, extension of the left border of cardiac dullness beyond the midclavicular line and systolic apical murmurs, and in two by basal systolic murmurs, edema of the ankles and coarse rales at the bases of both lungs. Numerous ventricular extrasystoles occurred in one instance and sensations of suffocation in the eighth month awakened another patient on several occasions, causing her to sit up. The symptoms of two patients were extreme. The dyspnea of one became so severe that the patient was unable to carry on her usual household duties. The other's symptoms were similar but were accompanied by marked apprehension, a coarse tremor of the hands, tachycardia and evidence of vasomotor instability. The arterial pressure was within the normal range in all patients. In each instance delivery was uneventful, and examination during the puerperium disclosed that practically all the signs and symptoms

had disappeared. So-called gestatory heart disease must be differentiated from organic heart disease as patients with the former type require no special treatment. The inclusion of patients with gestatory heart "disease" in the organic group not only causes them unnecessary expense, inconvenience and worry but exposes them unnecessarily to added obstetric risks.

Roentgenokymogram in Myocardial Infarction.—Sussman and his colleagues describe the kymographic abnormalities in serial records of 200 typical cases of coronary artery occlusion followed by myocardial infarction and correlate them with the various stages of the disease. In 75 per cent of the cases the following characteristic abnormalities were found: (1) diminution or absence of pulsation in a localized segment of the left ventricular contour, (2) systolic expansion, either total or partial, over one or more segments of the lower left contour and (3) diastolic splintering shown by marked irregularities in diastole. Equivocal changes included generalized diminution in pulsation, slight localized diminution in pulsation, slight irregularities in diastole and partial expansion not definitely in early systole. The early changes of myocardial infarction were studied in thirty-two patients on whom roentgenokymograms were obtained during the first or second week following the onset of coronary occlusion. In most of these cases serial roentgenokymograms were obtained at weekly or biweekly intervals. In ten of the thirty-two cases systolic expansion appeared as early as the first or second week. This persisted during the following three to eight weeks. Moderate to marked diminution in pulsation was present during the early stages in twelve. In nine the initial roentgenokymogram was normal or showed equivocal changes. Although the pulsations in the early stages were often normal or only slightly abnormal, in the majority of cases they became progressively impaired during the subacute stage, when complete or partial systolic expansion may be noticed in the fourth to the fifth week. Serial roentgenokymograms in a few cases showed that the cardiac contractions remained normal for two or three months, at the end of which time definite abnormalities finally became evident. This suggests that both softening of the ventricular wall by acute myomalacia and replacement fibrosis, with thinning, may be associated with abnormal ventricular contraction. Definite myocardial infarction produces no kymographic changes in a minority of cases. The incidence and type of kymographic abnormalities were the same in cases of recent and of old myocardial infarction. The incidence of abnormalities at intervals of from one to four years after recovery was approximately the same as during the acute stage of coronary occlusion. Of twenty-two patients examined from four to twelve years after the attack, sixteen still showed evidence of previous infarction in the form of complete or partial systolic expansion. Abnormalities in pulsation during the acute stage of the attack persisted, became more definite in the chronic stage or became less marked. Of thirty-four cases systolic expansion was observed in twenty cases during the acute or subacute stage of the attack, but it persisted in only eleven of these. Three follow-up roentgenokymograms were completely normal after recovery, and in six the systolic expansion regressed to diminution of pulsation with slight irregularities. Healing of the myocardial infarct may be followed by complete or partial disappearance of the abnormalities in ventricular contraction; this probably occurs when healing is associated with little residual fibrosis, which is a common postmortem observation.

Roentgenokymographic, Clinical and Electrocardiographic Correlation.—Dack and his associates correlated the roentgenokymographic changes, electrocardiographic changes and clinical course in 200 cases of acute and old myocardial infarction secondary to coronary artery occlusion. The kymogram was usually normal when the attack was mild and the recovery good. Regression or complete disappearance of kymographic abnormalities was a good prognostic sign. The kymographic abnormalities were usually marked when the attack was severe and the recovery incomplete. The roentgenokymogram and the electrocardiogram supplement each other, as one may be normal and the other abnormal, or vice versa. The roentgenokymogram should prove to be of most diagnostic value during the acute stage, when the clinical course and electrocardiogram are not typical of coronary artery occlusion,

and following recovery, when the characteristic signs of previous infarction have disappeared. Posterior infarction produced abnormalities in the postero-anterior kymogram as often as did anterior infarction. At autopsy, systolic expansion in four cases could be correlated with a large area of infarction or thinning of the left ventricle. Diminution of pulsation occurred in one case in which there was a small posterior infarct, and in another in which there was diffuse myofibrosis.

Hormone Etiology of Breast Cancer.—Cramer summarizes the results of his investigations on mice as follows: A high susceptibility to mammary cancer is associated in two strains of mice with a process of degeneration in the adrenal medulla. This susceptibility can be diminished by removing the supply of the adrenal cortical hormone or by applying an excess of an anterior pituitary substance. From this it is apparent that the susceptibility to mammary cancer is not a fixed and unalterable quality residing within the organism. It does not reside entirely—if at all—within the breast. It is conditioned partly by a disturbance of the endocrine balance. The estrogenic ovarian hormone acts as the carcinogenic agent and the synergic adrenocortical hormone without estrogen cannot exert its full activity. On the other side are the two hormones antagonizing the effects of the ovarian estrogen; the thyrotropic hormone of the anterior pituitary and a hormone from the adrenal medulla. The gap between a fully developed mamma and a cancerous mamma indicates that the process of carcinogenesis is not simply a continuation of development. The two are discontinuous. A new event—as yet unknown—takes place. The development of cancer in the mamma can be brought about by disturbing the endocrine balance in a variety of ways. In one the carcinogenic agent—the ovarian estrogenic hormone—is increased. This is the method used experimentally. When this is done the organism tries to restore the endocrine balance by a degenerative process in the adrenal cortex which tends to diminish the synergic hormone of the cortex and by an increased functional activity of the anterior part of the pituitary which secretes the antagonistic hormone. If the carcinogenic agent—the estrogen—is not increased, cancer may develop in the mamma as a result of a sensitization of the organism to the action of the ovarian hormone by a decrease in its antagonists. This is brought about in the two inbred strains of mice by a spontaneous degenerative process in the adrenal medulla or a pathologic condition in the anterior part of the pituitary may bring about dysfunction of the acidophil cells and thus weaken an antagonistic hormone. The existence of such pathologic conditions of the pituitary in association with mammary cancer has been recorded in the human being. Conversely, a resistance to the development of cancer in the mamma can also be brought about in a variety of ways. The carcinogenic agent may be diminished by ovariectomy; the effect of this procedure in delaying or preventing mammary cancer has been demonstrated. The same effect can be produced by diminishing the susceptibility by removal of the

synergistic adrenal hormone or by furnishing an 'excess of antagonistic anterior pituitary hormone. It is not known what factors switch over the carcinogenic action of estrogens from the mamma to other organs. The conception of an endocrine imbalance as an etiologic factor in cancer of the mamma, and probably also of the uterus, should serve as a useful guide for clinical investigations. There is now a possibility of treating precancerous conditions of these two organs by appropriate hormones. The uterine cervix being accessible seems to offer itself as a most likely object for such an investigation. It would be desirable to search for clinical features resulting from slight endocrinologic abnormalities which characterize women with an inherited susceptibility to mammary and to uterine cancer. If such susceptibility could be recognized clinically before the disease manifests itself, the endocrinologic abnormalities on which such susceptibility is based could be corrected, and these two numerically important types of cancer might be prevented.

Ovarian Dysgerminoma.—Sailer reports five cases of ovarian dysgerminoma in women aged from 10 to 21 years. Four of the tumors occurred in the right ovary and one in the left. This group represents an incidence of 6.1 per cent among a series of eighty primary malignant ovarian tumors. The predilection of the tumor for the right ovary and the age incidence appear characteristic of the dysgerminomas. The microscopic appearance, including the number of mitoses, appears to be an unreliable indicator of growth potentiality. All tumors were extremely cellular and showed a striking resemblance to testicular seminomas. One tumor, in a Negro girl of 10, recurred a year following removal, with extensive pelvic, peritoneal and probable lung metastases. Death occurred one year and eight months after removal of the primary growth. Three other patients are living and well without evidence of tumor, three, four and six years respectively after operation. None of those still living received roentgen therapy either before or after operation. One patient bore a child two years prior to removal of the tumor and had two normal full term pregnancies two and four years respectively following operation. The physiologic significance of the nests of granulosa cells among the dysgerminoma cells awaits further biochemical study.

Management and Treatment of Habitual Abortion.—Campbell and Sevringhaus used progesterone and corpus luteum extracts in the treatment of thirteen instances of habitual abortion. Each patient, with one exception, had aborted twice or more and did not have a living child. The exception was that of a woman who had a living child but aborted twice since its

birth. Following treatment eleven women went to term and had spontaneous deliveries. One patient aborted at the fourth month and the other at the sixth month of pregnancy. Each patient was carefully checked by physical examination and laboratory study to exclude every possible causative factor as related to habitual abortion. The eleven babies were not excessive in size and presented no fetal abnormalities. The progesterone dosage used varied considerably in the several cases and was quite high in the years before commercial preparations were available. The authors feel that from 1 to 2 rabbit units weekly is a safe dose for therapeutic effects. Others have used comparatively small doses. However the dosage necessary to prevent abortion is still empirical.

Spontaneous Pneumothorax in Newborn Infants.—DeCosta encountered spontaneous pneumothorax in two newborn infants. He suggests that it is a clinical entity which probably occurs frequently and is overlooked. No papers on the subject are to be found in obstetric literature, although references in the pediatric and roentgenologic literature do appear. A review of the literature reveals sixty-seven cases. Only forty-six of these have been directly associated with birth. In one of the author's cases subcutaneous emphysema and pneumoperitoneum were present. There appear to be two clinical types of pneumothorax in the newborn: one arises suddenly, demanding prompt treatment, and the other is more gradual and less severe with good prognosis irrespective of treatment. Resistance to the flow of air through the tracheal catheter during insufflation is suggestive of pneumothorax. The danger of producing pneumothorax by improper insufflation is stressed. Obstetricians should be mindful of the possible occurrence of pneumothorax, especially when artificial respiration has been employed.

Bronchiogenic Carcinoma.—Craver emphasizes the value of aspiration biopsy in the diagnosis of primary cancer of the lung and the value of roentgen radiation based on an analysis of 175 cases seen at the Memorial Hospital from 1918 to 1939 in which there was microscopic proof of the diagnosis. The diagnosis was proved at necropsy in thirty-four instances, from tissue removed at thoracotomy in eight, from expectorated macroscopic pieces of tissue in two, from tissue removed by bronchoscopy in fifty-nine and from aspiration biopsy in sixty. When a diagnosis of carcinoma is made after a carefully performed and interpreted aspiration biopsy and a clinical survey yields no sign of primary carcinoma elsewhere one is justified in assuming that the case is one of primary lung carcinoma. Bronchoscopy and particularly aspiration biopsy as proof of diagnosis

are brief, less hazardous and cause much less delay in subsequent procedures than thoracotomy. Removal of a biopsy specimen bronchoscopically is preferred to aspiration biopsy in all cases in which a bronchoscopic examination is feasible. Such tissue is more likely to show cellular arrangement and to permit a diagnosis of type, grade and radiosensitivity of the tumor more readily than the aspiration biopsy. However, the careful sectioning of the small clot or of gross tissue fragments obtained by aspiration biopsy may yield excellent sections. It was not possible to fit all cases into the three commonly accepted categories: epidermoid carcinoma, adenocarcinoma and anaplastic carcinoma. Two other groups were necessary: (1) bronchiogenic carcinoma, in which the growth is undoubtedly of bronchial origin but impossible of being classified as epidermoid carcinoma or adenocarcinoma, and (2) "carcinoma"—often the best diagnosis that can be made from the bits of tissue obtained by bronchoscopy or aspiration biopsy. The squamous and epidermoid group accounts for nearly half of the cases, bronchiogenic, adenocarcinoma and anaplastic growths each for about one tenth and the unclassified "carcinoma" for about one fifth of the cases. Follow-up of the 175 patients shows twenty living, 140 dead and fifteen untraced. Seventeen of the patients were untreated, two were operated on elsewhere, fourteen were treated with radon or radium packs and 142 received roentgen therapy. The duration of life after admission of the untreated patients averaged 2.4 months. The results of radium treatment were generally not favorable and the results of roentgen therapy show that, as the dose is increased in the initial cycle, the duration of life increases. Patients receiving from 2,000 to 3,000 roentgens in the tumor survived an average of 8.2 months, as compared with an average survival of only 4.3 months of those receiving less than 1,000 roentgens. There is a marked trend toward improved palliation as the tumor dose increases. The various microscopic types of carcinoma revealed no significant difference in the survival figures, but palliation seemed to favor the epidermoid group. One patient operated on ten months ago has gained 60 pounds (27.3 Kg.) and seems free of disease. For the remaining seventeen living patients treated by roentgen rays, the five year survival rates are discouragingly low. The five year survival rate is 3.8 per cent, the four, three and two year rates are respectively 4.4, 4.8 and 6.9 per cent. Roentgen treatment appears to be largely a matter of palliative effect and possible prolongation of life. One of the roentgen treated patients lived for 13.2 years.

Nitrates for Cardiospasm.—Ritvo and McDonald were able to relieve the esophageal obstruction of cardiospasm by administration of amyl nitrite or of glyceryl trinitrate. The effects of amyl nitrite were prompt in nearly every case. Glyceryl trinitrate was more variable and less effective yet proved more satisfactory for routine use because of the absence of side reactions accompanying the administration of amyl nitrite. Of the fourteen cases in which it was used partial or complete abolition of the stenosis resulted in eleven. Doses of $\frac{1}{100}$ grain (0.0006 Gm.), increased or repeated, were used when necessary without serious ill effects. The nitrates proved of no permanent curative value after repeated administration; however, the drugs have a definite though limited application in the treatment of cardiospasm. Patients with severe, chronic achalasia of the esophagus may lose much weight and become severely dehydrated and apprehensive. Vomiting and regurgitation with choking and severe coughing may cause pulmonary complications. In acute attacks the patient may actually struggle for breath and become cyanotic in attempting to dislodge a bolus of food by violent straining. Temporary relaxation of the stenosis may prove a life-saving procedure in cases of this type. The relief of the obstruction with the drugs, especially with glyceryl trinitrate, gives the patient relief from his distressing symptoms, it permits accurate roentgen visualization of the esophagus and the remainder of the gastrointestinal tract, the passage of dilators is facilitated and the danger of traumatism or perforation during instrumentation is lessened.

Radium for Carcinoma of Cervix Uteri.—Pitts and Waterman report the five year results on 135 patients with carcinoma of the cervix uteri treated with long platinum filtered radium needles of low intensity. The patients made up a consecutive series and all were treated in 1931, 1932 and

1933. A comparison of results obtained at the different clinical stages shows very little difference from the results obtained on the previously reported 173 patients treated between 1926 and 1930 by the interstitial method, in spite of the fact that more roentgen therapy was used on the last 135 patients. The five year survival rate in stage 3 cases for the first series was eighteen out of sixty-two, or 29 per cent; that for the 1931-1933 series was sixteen out of forty-eight cases, or 33.3 per cent. The five year survival rates for stage 2 cases were respectively 53.8 and 55 per cent and those for stage 1 cases 90 and 60 per cent for the 1926-1930 and the 1931-1933 series. The authors believe that the ability to deliver approximately 6,000 milligram hours of gamma radiation into the parametrial and paracervical tissues, in addition to the usual 3,000 milligram hours in the cervical canal, without tissue breakdown or other serious complication is the determining factor in producing good results in stage 3 cases.

Treatment of Trichomonas Vaginalis.—Karnaky recommends the following treatment after a microscopic diagnosis of trichomonas has been made, or when a patient complains of a foul malodorous discharge that causes itching or burning of the external genitalia and in all vaginal infections: The vulva, vagina and perineum are gently washed with vinegar water (5 tablespoons in 2 liters of water) and dried. From 1 to 2 drachms (4 to 7.8 Gm.) of a hydroxyquinoline derivative (floraquin powder) is blown into the vagina or from 4 to 8 tablets of the preparation are inserted, encircling the cervix, with a small plug of cotton inserted at the introitus. The patient is instructed to insert 1 tablet every morning and evening for twelve days. Instructions are given that a douche should not be taken during this period. After twelve days vinegar water douches (5 tablespoons of vinegar to 2 liters of water) are to be taken twice daily between and during the next three menstrual periods and up to the fourth menstrual period. At the end of the fourth menstrual period a fresh vaginal smear is made for trichomonas vaginalis and if found negative the patient is pronounced cured. If the smear is positive the treatment is resumed. Following each menstrual period for from two to five days 1 floraquin tablet is inserted morning and evening with vinegar douches as needed. Two tablets are inserted at the slightest itching or discharge and 1 tablet morning and evening for the next six days. The patient returns twice a week for two weeks for observation. For trichomonas vaginalis, pruritus vulvae or vaginitis with a great deal of tenderness from 1 to 2 drachms of the powder is blown into the vagina every day until the soreness is gone. An acid jelly can be inserted twice a day as a home treatment. After the acute stage has subsided 1 tablet is inserted

twice a day as home treatment. In 400 cases of trichomonas vaginalis in private practice and in more than 4,000 charity cases at the Jefferson Davis Hospital, 94 per cent of the patients were cured by this method.

Acute Miliary Infarction of Heart.—Lisa and McPeak direct attention to an acute lesion of the myocardium called miliary infarction, which was found in ninety-nine cases and was usually associated with the clinical syndrome of sudden left ventricular failure. The material reviewed consisted of 2,857 cases in which necropsy was performed; it was divided into two main groups: (1) cases in which coronary arteriosclerosis was present and (2) cases in which this condition was not present. The first group was subdivided into a cardiac sclerotic group and a noncardiac sclerotic group on the basis of clinical symptomatology. The acute miliary infarction was most frequent in the cardiac sclerotic group, much less so in the noncardiac sclerotic group and least frequent in the nonsclerotic group. In the cardiac sclerotic group, its incidence was equal to that of acute coronary thrombosis. The greatly hypertrophied heart with marked sclerosis of the coronary arteries seemed most susceptible to the occurrence of the lesion. In seventeen of the ninety-nine cases, thrombi or emboli of the myocardial branches of the coronary arteries were found. The thrombosis was bacterial in one instance and malignant in another. In one case thrombosis of a main coronary artery was caused by a bacterial embolus arising from acute lobar pneumonia. An infectious nature of the myocardial lesion itself was never demonstrated. Infections in other organs, most frequently the lungs, were present in the majority of cases. The authors think that the lesion in the majority of cases is toxic and in a small percentage is due to embolism or thrombosis of the muscular branches of the coronary arteries, usually, even in this group, associated with infection.

Sulfanilamide in Urinary Infections Due to Bacillus Coli.—Rantz and Keefer present a study of treatment with sulfanilamide in seventeen cases of infection of the urinary tract due to Bacillus coli. Clinical improvement and sterilization of the urine were accomplished in most instances; the best results were obtained in cases in which there was no previous history of urinary infection and in those in which the infection was associated with pregnancy. If evidence of chronic infection of the urinary passages was present, the urine was more difficult to sterilize, and relapse frequently occurred. The urine usually could be sterilized by the oral administration of from 2 to 5 Gm. of sulfanilamide in twenty-four hours; this dose resulted in concentrations of from 23 to 139 mg. of the drug per hundred cubic centimeters of urine. No definite correlation was demonstrable between the dose of sulfanilamide, its concentration in the urine and the permanence of cure. The usual toxic symptoms associated with the administration of sulfanilamide were observed. Anemia appeared when the drug was exhibited in the presence of fever but usually did not recur when it was admin-

istered in the absence of fever. Seven strains of *Bacillus coli* isolated from the urines were studied in vitro. Sulfanilamide had bacteriostatic and, in certain instances, bactericidal effects; there were great differences in sensitivity to the drug between the various strains. Optimal bacteriostasis was obtained with concentrations of more than 80 mg. of sulfanilamide per hundred cubic centimeters of urine. To increase its concentration above 160 mg. did not significantly increase the drug's effectiveness. The p_H of the urine did not affect the activity of the drug in vitro. No correlation was demonstrated between the activity of sulfanilamide in vitro and that in vivo. Mandelic acid in vitro was markedly bacteriostatic for all strains, but in vivo it was not as effective as sulfanilamide.

Generalized Sarcoidosis of Boeck.—Harrell observed eleven patients with generalized sarcoidosis over a period of four years. Two have been clinically well for two years. Negroes predominated in this group. Changes were found in the content of calcium, protein and phosphatase of the blood. The phosphorus and nonprotein nitrogen were not altered. The cholesterol content was usually low or normal in cases in which the condition was active. Bilirubin tolerance tests showed retention. Calcium tolerance tests gave varied results. Substances resembling Bence Jones protein were occasionally present in the urine. Etiologic studies, with emphasis on fungi and acid-fast bacilli, using animal inoculation, cultures and serologic and cutaneous tests, gave negative results. The cutaneous test suggested by Williams and Nickerson did not give positive results. It is possible that some unrecovered member of the general group of bacteria related to the actinomyces, the leprosy bacillus or the tubercle bacillus is the etiologic agent, but as yet the etiologic question remains unsolved. It is suggested that the reaction may be an exaggerated nonspecific response to a lipid fraction of various organisms. Hematologic studies confirmed low or normal white blood cell counts, neutropenia (without a shift to the left in the Schilling hemogram), eosinophilia, monocytosis and increased sedimentation rate. Occasional nonspecific changes were observed in the electrocardiogram. The pathologic picture varied from a complete absence of eosinophils, the presence of moderate numbers of giant cells in acute lesions and the occasional presence of necrosis and amyloid. The treatment was empiric. The patients were advised to take a high calory, high vitamin diet, with cod liver oil and tomato or orange juice, to rest and to remain in the sunshine as much as possible. Ultraviolet irradiation produced no permanent improvement. Hyperpyrexia and sodium gold thiosulfate produced no noticeable benefit. Intravenous injection of nearsphenamine was credited by a patient with causing improvement. Other patients had received this drug before they were seen or have since received it in treatment of syphilis, with no benefit. Desensitization to Williams and Nickerson's antigen might be tried on patients who react positively on cutaneous test to it. The maintenance of the blood of the patients near saturation with vitamin C caused no immediate improvement.

Artificial Fever and Sulfanilamide in Gonorrhea.—Belt and Folkenberg treated 134 gonorrhea patients with artificial fever, sixty-eight with fever and sulfanilamide and five with temperatures equal to the thermal death time of the gonococci. Twenty-nine of the 134 patients did not complete the single ten hour session. Five were given fever longer than ten hours. One hundred patients received a single hyperpyrexia treatment of ten hours at a rectal temperature of 106.7 F. Eighty-seven of these were found on a follow-up to be consistently free of gonococci. The 134 cases receiving only fever therapy represented every complication of gonococcal infection: prostatitis, cowperitis, epididymitis, seminal vesiculitis, periurethral abscess with fistulas, arthritis, salpingitis, Bartholinitis, proctitis, peritonitis, ophthalmia, septicemia and endocarditis. All complications except endocarditis responded well to treatment. Sulfanilamide and its related compounds, combined with mild local treatment, were effective in 80 per cent. The authors resorted to fever therapy in sulfanilamide-resistant cases. Sixty-eight patients were given 20 grains (1.3 Gm.) of sulfanilamide four times daily for two days preceding fever therapy. On the morning of the fever treatment the patient takes 20 grains of sulfanilamide one hour before reporting. A fever session of five hours is given every other day until three treatments have been given. Sulfanilamide, 20 grains, is administered four times daily on alternate days. This combination therapy cures 86 per cent of the 20 per cent not cured by sulfanilamide alone. A combination of the two figures demonstrates success in 97 per cent of the cases. For the few cases (five in number) not cured by the combined therapy; fever equal to the in vitro thermal death time of the patient's own strain of gonococcus is suggested. This method will result in an incidence of cure approaching 100 per cent.

Hysterosalpingectomy for Chronic Salpingitis.—McDermott analyzes results in sixty patients from the Los Angeles County Hospital, all of whom had had bilateral salpingectomies for chronic salpingitis and later had to have hysterectomies. He believes that for every one of these there must be several who suffer from symptoms due to the "left-over uterus" but who are so discouraged by the poor results of their one operation that they refuse a second; or there must be those whose symptoms are not quite sufficient to justify another major procedure. The argument of the proponents of conservatism favoring the preservation of the child-bearing function is pertinent only when plastic operations on the tube or unilateral salpingectomy are performed. The author believes that the chances of success are slight. The second argument, that of the physiologic value of the uterus, is met by the answers that the psychologic importance of menstruation is overestimated and that there is no proof that the uterus has an endocrine function, its only known purpose being that of child bearing. The argument of the technical difficulties of hysterectomy is refuted by the facts. To conserve an organ may or may not be conservative as far as the welfare of the patient is concerned. Incomplete surgery is often given standing by being labeled conservative.

Lung Abscess.—Fisher and Finney report the results of various types of treatment in eighty-eight cases of lung abscess. All but five of the patients, who were between 3 and 6 years of age, were adults up to more than 61 years of age. Fifty patients either improved or recovered completely, and thirty-eight either died or failed to improve. The duration of the abscess is of great importance. Many patients get well spontaneously if the duration prior to admission is less than two months. The percentage of unsatisfactory results rises rapidly and progressively thereafter. The majority of lung abscesses are due to atelectasis and aspiration of infected material from the upper part of the respiratory tract. A much smaller proportion is due to infected pulmonary or sterile emboli followed by aspiration of infected material. Contributing factors are oral sepsis, alcoholism and malnutrition. The flora in the material from abscesses varies from case to case. Anaerobes and facultative anaerobes are frequent. The alpha-hemolytic (viridans) streptococcus is prominent in the sputum; it is at times aerobic and at other times facultatively anaerobic. Anaerobic streptococci are most often found in cultures of material obtained from the abscesses or from complicating empyemas. Anaerobic gram-negative bacilli are also frequently found in the abscess or empyema fluid. In most lesions a symbiosis of several varieties is encountered. Eradication of infections in the nose, throat and mouth, especially before operation, should lower the incidence of lung abscess. The type and depth of anesthesia and the position of the patient during operation are important. Other prophylactic measures are aspiration of secretions from the trachea during and after operation and postoperative inhalations of carbon dioxide and oxygen by patients not acrating their lung bases well. Postural drainage should be as nearly continuous as practical. When the sputum contains many spirochetes, arsenicals intravenously may yield dramatic results. Repeated therapeutic bronchoscopy is usually not indicated. Pneumothorax is useful only when the lesion is close to the hilus. Surgical treatment should

provide adequate drainage without contaminating the pleural cavity. This can usually be accomplished by a two-stage operation, the cautery being used for incision into the abscess. The chief barriers to successful treatment in the chronic abscesses are thick, rigid, fibrous walls which prevent collapse of the cavities, eroded blood vessels with recurrent hemorrhages, intrapulmonary spread or metastatic abscess formation and the unfavorable effect of the chronic infection on the patient's general condition. Acute fulminating abscesses usually lead to death in from a few days to a few weeks, in spite of treatment. Putrid empyema or pyopneumothorax was present in nine cases. Some form of closed drainage is the best means of dealing with these complications. Chronic alcoholism makes the prognosis much worse. All six patients with such a history died. Operations in the presence of oral infection is hazardous. There were four such cases, all fatal.

Skin and Ocular Reactions in Sulfathiazole Therapy.—During the first three and one-half months of sulfathiazole therapy in their clinic Haviland and Long encountered ten cases of cutaneous eruptions in a total of seventy-eight patients. The reactions appeared after the compound had been administered for several days. All the eruptions cleared rapidly, coincident with the disappearance of the drug from the blood stream. They were almost always accompanied by one or another of the companion signs of a sulfonamide reaction. The rashes fall into three groups: maculopapular, urticarial and erythema nodosum. The last two groups may merge into one another. They are quite different from the eruptions which follow the use of other sulfanilamide derivatives. The urticarial reactions involve the skin of the extremities, although the trunk was not spared when the rash became extensive. The involved area was raised, red, well outlined and irregularly thickened. As the lesions faded, they left a reddened area at the site for a few days, but even this soon faded. The reactions likened to "erythema nodosum" were more advanced stages of the so-called urticarial lesions. They were described as typical of "erythema nodosum" when knowledge of the medication was lacking. When the nodules regressed they did not turn dusky and reddish blue. There was no local discoloration. One entirely new type of drug reaction has been observed in this group. The lesion is a conjunctival and scleral injection, restricted in the main to the exposed portions of the bulbar conjunctiva and sclera. The injection has been extreme in six cases, with considerable burning and a watery discharge from the affected eye. Four of the six cases occurred in conjunction with the drug eruption, while two were seen as isolated phenomena. In three cases, the eye nearest the light was disturbed either solely or primarily. In two cases in which exposure to light was great the eruption and conjunctivitis were much more severe, involving the exposed surfaces and even the palpebral conjunctiva. There was no recrudescence of the conjunctivitis on exposure to light after sulfathiazole had been discontinued. That this reaction did not invariably follow exposure to light is shown by the fact that several other patients were exposed to winter daylight during the course of sulfathiazole therapy without untoward results. In view of the apparent relationship of some of these reactions to exposure to light, the question of light sensitivity as an etiologic agent in sulfonamide reactions is again raised.

Sulfamethylthiazole for Furunculosis.—Grulee and Mason used sulfamethylthiazole for the treatment of three children with furunculosis of the scalp. Improvement began within from twenty-four to forty-eight hours. The furuncles of one child were almost completely healed in six days; in the others new lesions developed when the drug was discontinued, but all cleared up after a total of thirteen and twenty-three days of treatment, respectively. The dosage used was from 0.5 to 1 Gm. every four hours. The infant who required twenty-three days of treatment had the most severe case of furunculosis ever seen by the authors. The child had been hospitalized when 2½ months old and treated variously for eight months, with no apparent improvement. On the tenth day after sulfamethylthiazole was started in this case the abscesses still showed positive cultures. Vomiting, toxic rash and neutropenia developed in two of the children, but all this cleared up without serious after-effects.

Tetany in Infancy and Childhood.—Chu and Sung report the results of vitamin D and calcium therapy in forty-five cases of tetany in children from birth to 12 years of age. The following features had to be present: hypocalcemia (serum calcium content of 8 mg. or less per hundred cubic centimeters), typical attacks of spontaneous carpopedal spasm and other manifestations of tetany, such as convulsions, muscular spasms, Trousseau's sign, Chvostek's sign or Erb's sign. This material differs from cases reported in the Western literature in that the onset of tetany in thirty of their children occurred in the first three months of life and also in that their tetany patients often show rickets, even if they are no older than 3 months. These differences are explained by the fact that the mothers who bear and feed these children suffer from abnormal vitamin D metabolism. Twenty-six of thirty-five children who

had x-ray examinations of the long bones showed rachitic signs of varying degrees, mostly moderate and mild. Clinically, twenty-one of these children were rachitic. Calcium therapy alone may elevate the serum calcium temporarily, but the active symptoms of tetany will recur until vitamin D is supplied in sufficient amount. Therefore antirachitic treatment should be instituted simultaneously or a few days after calcium therapy is begun. Concentrated preparations of vitamin D bring the serum calcium to a normal level within a short period. Fifty per cent of the patients were breast fed before tetany developed. In a community in which the mother's nutrition is usually not adequate, human milk should not be relied on to protect the sucklings from tetany. The case fatality of the series was 20 per cent. The chief causes of death were various infections in six, neoplasm of the liver in one, "idiopathic hypertrophy of the heart" in one and probably laryngospasm in another case. Except for the latter case,* none of the deaths were directly related to tetany. Uncomplicated cases of tetany, if correctly diagnosed and appropriately treated, have an excellent prognosis.

Results of Thoracoplasty.—O'Brien and his associates performed a total of 1,404 operations on 511 patients from August 1932 to Dec. 31, 1938. The disease was unilateral in 202 cases and bilateral in 309. Ninety-seven patients had contralateral pneumothorax at the time of thoracoplasty. The disease was predominantly productive in 368 cases. It was mixed in 104 and exudative in thirty-nine. Four hundred and ninety-six patients had cavernous lesions. Thoracoplasty was done in fourteen cases for closure of tuberculous empyema. With few exceptions the first stage consisted of complete removal subperiosteally of the upper three ribs through a posterior incision. Successive stages were performed at three week intervals, long sections of two or three ribs being removed at a stage until the desired amount of collapse was obtained. Only infrequently has it been necessary to subject the patient to more than four stages. The fifth and sixth stages represent secondary operations or revisions. Anterolateral stages were done in forty-nine, and secondary operations (revisions) were necessary in seventy-one. The immediate fatality rate (within eight weeks after operation) was 9.39 per cent; the late fatality rate (from two months to six and one-half years after operation) 9.78 per cent, the total 19.17 per cent. Cavity closure was effected in 87.02 per cent and sputum conversion in 81.65 per cent. In 187 cases the condition has apparently been cured, in eighty-two it has been arrested, in forty it has been apparently arrested, in twenty-six it is quiescent and in forty-nine it is unstable, and twenty-six cases are untraced. Of 296 patients at home, 224 are working or are able to work. The experience with thoracoplasty in the very young (youngest patient 8 years) has been disappointing. Although gratifying results have been obtained in the adolescent group so far as cavity closure and sputum conversion are concerned, the authors have been reluctant to subject these patients to thoracoplasty because of the possibility of marked deformity. Extrapleural pneumothorax may prove to be a valuable procedure in controlling, at least temporarily, the lesions in this group of patients. The fatality rate was only 3 per cent greater in the exudative than in the productive type of lesion.

Extrapleural Pneumothorax and Oleothorax.—Proctor considers extrapleural pneumothorax a valuable addition to thoracic surgery because it provides a chance for recovery in many otherwise hopeless cases. If permanent collapse is desired, the diseased area should have oleothorax, which attains the goal of a permanent filling. In the majority of his forty-four cases, extrapleural pneumothorax has been converted into oleothorax. When it is intended from the start to use oil as a permanent means of keeping a localized area of lung compressed an extrapleural pneumothorax is established first. Two or three months later, when the extrapleural space is of the size and location desired, it is filled with oil. The extrapleural space may be varied in size by the amount of pressure used in the refills. The best procedure is to make the original space larger than one contemplates leaving it and with the use of less pressure allow the lung to reexpand to the desired point. Olive oil or liquid petrolatum may be used with or without the addition of cajuput oil. In many instances it may be preferable to use liquid petrolatum to obviate refills. The extrapleural space is filled in three or four sessions, depending on the size of the space. Additional oil may be added every six to twenty-four months. Additional pleural pneumothorax with oleothorax presents advantages over thoracoplasty.

Patent Ductus Arteriosus.—Jones and his associates report clinical observations on seven patients with patent ductus arteriosus in whom they performed surgical ligation. Six patients were between 4 and 13 years of age and one patient was 31. All except the adult showed a high pulse pressure with low diastolic blood pressure. The diastolic pressure was often difficult to measure. One of the patients had a classic Corrigan pulse and pistol shot sound over the femoral artery. Another patient had these signs appear only after exercise. Another had typical physical signs and laboratory evidence of a patent ductus arteriosus. The most important sign of the condition is a continuous murmur in the pulmonic area, varying in intensity during each cardiac cycle and usually accompanied by a thrill. Increase of the pulmonary second sound, prominence of the pulmonary conus on x-ray examination, absence of cyanosis, increase of pulse pressure with low diastolic pressure and absence of axis deviation in the electrocardiogram are usually present as confirmatory aspects. The authors describe the surgical technique and review the operative and postoperative courses. They conclude that these cases must be followed over a long period before the described procedure can be adequately evaluated. They have successfully ligated a patent ductus arteriosus in six additional cases, bringing the total to thirteen.

Urologic Complications of Sulfapyridine.—Antopol states that sixteen of forty patients with pneumococcal pneumonia receiving sulfapyridine showed a transient microscopic hematuria. X-ray examination of two patients with considerable hematuria revealed a urolith. This is in accord with the experimental studies in which the concretions are radiotransparent. A secondary deposition of a calcium shell occurs after

the calculus has been present for a long time. The concretions are soft and friable and can be either redissolved or washed out. The entire urinary output was collected and examined daily. This revealed a hematuria varying from 2 to more than 100 erythrocytes per high power field, with most cases containing between 3 and 5 cells. In 100 collected cases of pneumococcal pneumonia before the advent of sulfapyridine therapy, erythrocytes were found in specimens of urine of only eleven patients; in six of these there was less than 1 erythrocyte per high power field and in the other five less than 3 cells. In the sulfapyridine group of patients whose urine was examined before or in the early period of therapy no erythrocytes were found. The hematuria was usually detectable in from one to three days after sulfapyridine therapy was initiated and disappeared shortly after it was discontinued. No residual symptoms were exhibited by any of the surviving patients. In one instance no concretions were demonstrable at necropsy in the urinary tract. However, there was a pronounced localized non-necrotizing hemorrhagic papillitis and pyelitis and severe tubular degeneration in the adjacent areas. The degenerative renal changes corresponded with those found in animal experiments. It is not unlikely that the lesions found at necropsy, as well as the cause of the hemorrhage in one case, may have been primarily renal degenerative or vascular and noncalculous in nature. Because of this possibility and because blood clots have been found to be the cause of obstruction in some of the experimental animals, the latter might well have been the cause of the colicky pain which radiated from the lumbar region anteriorly to the groin, complained of by one patient. Gross hematuria was present at this time. X-ray examination of the abdomen revealed no calculi. Fluids were forced and the hematuria cleared up in four days. There were no residual signs.

Cancer of Lip.—Hunt states that any progressive or persistent "sore," "fever blister," "crack" or "lump" on the lower lip which does not heal in three weeks must be considered cancer until disproved by biopsy or darkfield examination. Cancer of the lip is fifty times as prevalent in men as in women. Many extraneous factors hasten its development in a susceptible person. Sunburn should be avoided. Repeated blistering of the lip and skin by sunlight or ultraviolet rays is definitely injurious and probably accounts for the unusually high incidence of cancer of the face in the farming population. The overwhelming predilection of cancer for the lower lip, occurring in 98 per cent of the male cases, is in keeping with the relatively greater exposure of the lower lip to sunlight and other disturbing influences. Other probable precipitating causes may be repeated burns from short cigarets, short stemmed pipes, overly hot foods, snuff, mechanical irritation, overhanging, sharp, irregular upper incisor or cuspid teeth, and repeated chapping and cracking by wind, weather and sun. All chronic lesions showing continued overgrowth of tissues are eventually precancerous lesions and should be eliminated. Leukoplakia should be eradicated, particularly in case of ulceration or extension. A papilloma or keratotic horn should be treated as a low grade carcinoma. Correctly administered, roentgen and radium therapy are as effective as surgery in controlling the primary lesion in cancer of the lip or skin. The first series of roentgen or radium treatments must be correctly applied if success is to be attained, as the lesion will never respond as well to subsequent irradiation of equal intensity. This loss of radiosensitivity is due to impaired blood supply and fibrosis of the bed of the tumor. Radiotherapy usually gives a better cosmetic result than surgery and better preservation of function, particularly in the large papillary tumors. Roentgen and radium therapy give essentially the same biologic effect and differ primarily in distribution of intensities. The therapeutic agent will depend on the gross morphologic changes of the lesion, history of previous treatment, the grade of the tumor, the antipathies of the patient and the experience of the therapist. The small superficial lesions are treated by low voltage x-rays or by radium plaque. The infiltrating cancers are treated by intermediate voltage x-rays supplemented by interstitial radium in the deeper lesions. The large papillary tumors are treated by intermediate or high voltage, lightly filtered x-rays supple-

mented by interstitial radium through the base of the tumor. Occasionally the pendulous portion of the large tumor may be ablated to expose the base, but this is not necessary. In the ulcerating destructive lesion with extensive sloughing away of the lip, the author prefers immediate wide surgical excision followed directly by plastic repair. Local invasion of bone is treated by electrocoagulation with or without local excision. In persistent or recurrent carcinoma after inadequate radiotherapy, surgical resection, in view of acquired radioresistance, is generally advised. A radiation ulcer which persists after four months is best resected and plastically repaired. Metastases from cancer of the lip occur first in the submaxillary and submental nodes and rarely in the cervical nodes without gross involvement of the suprahyoid triangles. Cancers arising at the corners of the mouth tend to metastasize unusually early. Enlargement of lymph nodes suggests metastases but frequently is due to inflammation secondary to ulceration and infection of the cancer. Metastases are present in about 25 per cent of patients with palpably enlarged but movable nodes. Metastases will develop in about 10 per cent of patients showing no initial adenopathy. The prospects of a "five year cure" are from 90 to 95 per cent without apparent metastases, 33½ per cent with an early single focus of metastasis in the suprahyoid structures and only 1 per cent after metastases are present in the cervical lymph nodes.

Nitrogen Gas Convulsive Therapy.—Halvorsen used pure nitrogen in the convulsive treatment of schizophrenic and involutional depressions. He believes that for patients in the upper age brackets with brittle bones gas convulsions have a wider margin of safety than convulsant doses of metrazol. Gas convulsions are less severe and therefore the dangers of vertebral and extremity fractures are lessened. The patient is given insulin sufficient to produce coma and in about two hours, when myoclonic jerks occur, pure nitrogen gas is administered by mask through a rebreathing bag. All mask outlets are closed. No atmospheric air is admitted. The lime filter is shut off. In

from one to two minutes cyanosis appears and gradually deepens. Tonic stiffening begins on an average of from three to four minutes, noticeable first in the small muscles of the eye, fingers and toes. The tonic convulsion includes all the body muscles during the next thirty seconds. The end point of maximal tonic spasm is apnea due to respiratory muscle spasm when the mask is removed and the patient is turned to the prone position. This serves to drain saliva and prepare the patient for artificial respiration. The apnea is permitted to last as long as it can to accentuate the asphyxia. The patient's color returns to normal within from five to ten seconds after respiration begins and sufficient glycogenolysis usually follows to neutralize the insulin and awaken the patient from the coma. On awakening, the patient eats his withheld breakfast with relish. A tendency toward jovial sociability replaces the pretreatment dulness. Out of twenty-two convulsions given seven patients one patient had a headache. There have been no osseous injuries and while muscular stiffness occurs this is not the extreme soreness that follows metrazol convulsions. Rapid improvement toward normal personality occurred and this without the reactions of fear that metrazol produces. Nitrogen produces anoxemia (the principle of shock therapy) which leads to a tonic convulsion.

Bacterial Endocarditis Among Lepers.—According to Lara, the most frequent type of endocarditis among lepers in Culiön is that caused by a gram-negative *diplococcus bacillus* which Solis had invariably obtained in blood cultures from certain cases of septicemia. This organism produces an infection of two to four weeks' duration, with the development of large valvular vegetations resulting in septic embolic phenomena in the spleen and the kidneys, with fever, leukocytosis, secondary anemia and an invariably fatal outcome. The incidence of the disease is higher than with other types of bacterial endocarditis. Current books on pathology, bacteriology and internal medicine make no mention of it. This type of endocarditis occurs in only one place in the world—Culiön, Philippine Islands. Its occurrence in a small number of the several thousand lepers confined in the colony, as well as its distinct morphologic and cultural

characteristics, leaves no doubt that it is an entirely different organism. No distinctive epidemiologic peculiarities are apparent. How the organism enters the body is not known. The disease occurs in lepers whether they have ulcers or not. The microscopic appearance of the valvular vegetations is that of a superficial layer of fibrin in which are enmeshed erythrocytes and leukocytes, many of which are in a degenerating condition. Beneath this layer is a dense bacterial growth and, still deeper, a formless debris of fibrin, erythrocytes, leukocytes and probably dead bacteria. The rest of the endocardium and the epicardium is studded with petechial hemorrhages or larger ecchymoses. An acute myelomalacia is the rule. The spleen is enlarged and softened, with multiple red or pale infarcts on its outer parenchyma. The liver and the kidneys are enlarged, soft and pale. The peritoneum may be involved in a septic peritonitis, particularly that portion adjacent to a surface infarct of the spleen. There is a secondary anemia and a leukocytosis. The adrenals present acute infectious softening. The causative organisms are readily isolated by blood cultures. Smears and sections always show their presence in the valvular vegetations, less constantly in the parenchyma and in the infarcts in the spleen. Quite suddenly, without any history of an infected wound, the disease is ushered in with general body and joint pains, fever and headache. In about a week a moderate to high fever, remittent or intermittent, ensues and probably some precordial pain. A blood culture at this time will reveal abundant numbers of the organism. The precordial complaint becomes more marked every day, and cardiac murmurs appear. Embolic phenomena appear at various places, most constantly in the spleen, which is enlarged. No medicine available and tried in Culion was able to save a single patient. Treatment consists of careful and diligent nursing and the relief of symptoms.

Tularemia.—This article reports 2,088 cases of tularemia with 139 deaths which occurred in the United States during 1938. Wild rabbits and hares are the direct cause of more than 90 per cent of cases in human beings in the United States. Horseflies have caused cases in Utah and wood ticks in Montana and the surrounding states. The dog tick has caused cases, principally in the Southern states. Contact with sheep has

caused cases in the Northwest among shearers, butchers and herders, the infection entering the hands from contact with wood ticks and tick feces located in the wool. Sheep are only slightly susceptible. Insect bites (species undetermined) caused tularemia. One infected person had picked ticks from a dog and crushed them with his fingers. Skinning or dressing of tree squirrels, opossums, sage hens, coyotes, deers, red foxes, bull snakes, quails, ground hogs, muskrats, hogs or skunks has been followed by tularemia. Scratches or bites from cats or raccoons, dissection of infected laboratory animals or eating of insufficiently cooked wild rabbit meat has caused tularemia. A water-borne epidemic was reported in 1935 from Russia. Early in 1940, officers of the U. S. Public Health Service reported that water in three streams in Montana had been found to be contaminated with *Bacterium tularensis*. The organism may be transmitted from one animal to another and from animal to man by the bite of insects, notably the wood tick, the dog tick and the deer fly. The pelts of infected rabbits and other animals may also convey the infection. About three and one-half days after exposure illness begins suddenly with headache, chilliness, vomiting, fever, prostration and aching pains all over the body. The symptoms are often mistaken for those of influenza. The sore, usually on the hand, develops into an ulcer, and the nearby lymph glands, at the elbow or in the armpit, become enlarged, tender and painful and later may develop into abscesses. Illness and fever last for about three weeks. Convalescence is slow and is characterized by great weakness and disability, which may continue for two or three months. Most patients recover without permanent ill effects, but about 5 per cent die, notably those in whom pneumonia develops. One attack of the disease confers immunity. Hunters, vacationists, butchers, housewives and laboratory workers who handle rabbits and other wild game are especially exposed to tularemia. A wild rabbit should never be handled with bare hands. Only immune persons should be employed in laboratories. The infected meat is rendered safe as food by thorough cooking. Refrigeration for ordinary periods does not kill the tularemia organism. There is no specific preventive or curative treatment for the disease.

*Cancer Mortality in the United States According to Site, by Sex and Age, 1938.—p. 731.

Cancer Mortality in the United States.—Statistics recently issued by the U. S. Bureau of Census record a total of 149,214 deaths from cancer in this country in 1938; 69,857, or 47 per cent, of these occurred in men and 79,357, or 53 per cent, in women. During the four years 1934-1938 the increase in recorded mortality from cancer amounted to 10.5 per cent, as compared with an estimated increase of 2.8 per cent in the population. An increase of 13 per cent is shown for men as compared with 9 per cent for women. The largest percentage increase was recorded for cancer of the respiratory system (52 and 39 per cent for men and women respectively), while broad classification groups showed a decrease for cancer of the buccal cavity and pharynx (for both sexes) and cancer of the skin (for men only). Cancer of the digestive tract and peritoneum caused 47 per cent of the total cancer mortality in 1938. The number of deaths from cancer of the various sites in this classification increased 9.3 per cent for men and 6.8 per cent for women during the four years. Deaths from cancer of the genito-urinary organs (uterus excluded) increased by about 20 per cent for both sexes. Cancer of the uterus (which caused 20 per cent of all cancer mortality in women in 1938) increased 4 per cent, while cancer of the breast increased 10 per cent during the four years. Of the 149,214 deaths from cancer 719 were of patients less than 10 years of age, and respectively for the following decades: 743, 1,985, 6,296, 17,477, 31,541, 41,244, 35,871, 12,289, 1,000, and the age of forty-nine patients at death was not stated.

Roentgen Therapy for Bone and Joint Pains.—Ochsner and Mumford report the results of roentgen therapy on ninety patients with osseous and joint pain from trauma, arthritis and infection. Of fifty-two suffering from pain as a result of trauma, twenty-seven had fractures, fourteen trauma but no fracture, five painful joints following surgical procedures, four were probably due to muscular strain, and two had painful extremities with limitation of joint motion following infected burns. Best results were obtained in cases of postoperative pain. Pain disappeared in only one of the patients with no specific injury other than possible muscular strain and three experienced no improvement. Of the twenty-seven patients with painful joints following fracture, 56 per cent obtained improvement while 64 per cent of the group with traumatic injuries but no fracture were improved. Amelioration of pain and diminution in stiffness occurred most frequently during treatment but in a number of instances was not appreciable until weeks afterward. Only 7 per cent had a temporary exacerbation of symptoms. In the traumatic group, with or without fracture, the improvement was in most instances permanent, although a few patients had recurrence of symptoms after three or four weeks. Two or even three courses of treatment were required to obtain optimal benefit. Of thirty-five patients suffering from arthritis bursitis, fibrositis, vertebral osteoporosis or sciatic neuritis, twenty-nine obtained some improvement. Eighty-seven per cent of the twenty-three patients with atrophic or hypertrophic arthritis obtained relief; in the atrophic group the improvement was marked in all but one of eight patients, and this patient was slightly improved. In general, more than one course of treatments was recommended for arthritis because of its chronic and recurrent nature. The effectiveness of roentgen therapy for cellulitis that sometimes follows dental extraction was demonstrated by the prompt relief of discomfort in one case. All patients were treated with roentgen rays generated at 200 kilovolts and 25 milliamperes of current. A filtration of 0.5 mm. of copper and 1 mm. of aluminum was used, with a skin target distance of 50 cm. and fields varying in size according to the part treated. Four applications of 100 roentgens have been given with an interval of two or three days between treatments. While the authors do not regard the method as a cure-all, they believe that more improvement was obtained than could have been effected by other therapeutic measures.

Relative Value of Suture Materials.—Meade and Ochsner studied the tensile strengths of catgut, silk, linen and cotton, and the tissue reaction and wound healing caused by each. Catgut was demonstrated to be (1) a strong suture before being placed in tissue, (2) absorbed at a variable rate which depends on its size, the chemicals present and the reaction of the individual, (3) a possible source of allergic reactions, (4) a deterrent in wound healing, (5) unreliable when knotted under tension unless triple or quadruple throws knots are tied and (6) above all, a possible cause of wound infection. Nonabsorbable suture materials can always be heat sterilized; they produce no allergic reactions, allow rapid wound healing and reliable square knots can be tied. While silk and linen show early decrease in tensile strength as compared to cotton, they also are stronger before implantation. Cotton and linen, as products of the field, may contain spore-forming anaerobic pathogens, but the average threads obtained on the market have not contained any pathogenic organisms. Silk contains the ordinary pyogens, but anaerobic organisms were not found. Chemically treated silk and catgut are proteins; the former, being nonabsorbable, excites must less tissue reaction. Sinuses may develop in wounds sutured with silk in the presence of infection (not contamination) and they will not heal until the suture is removed or expelled. There is little difference in the wound healing when serum-proofed and nonserum-proofed silk is used. Braided silk has greater tensile strength than twisted silk. Cotton shows much less tendency for tissue ingrowth than silk and therefore, in the presence of infection, is less likely to cause sinuses. Cotton is proposed as a pliable, easily sterilized, nonirritating, inexpensive suture of sufficient strength in the recommended sizes for most surgical procedures. It has been used in ninety-one surgical procedures, primary healing having taken place in eighty-eight. Halsted's silk technic is recommended not only for silk but also for cotton. The reaction of tissue to the implanted suture was graded according to the amount and persistence of leukocytic infiltration, amount of serum and fibrin, the appearance time of fibroblasts and length of time necessary to produce final healing. Catgut, by producing the most reaction and slowest healing, was graded 4, linen 3, silk 2, and cotton, producing the least reaction and earliest healing, 1.

Trigeminal Neuralgia.—Livingston states that injections of procaine hydrochloride for facial pain have given encouraging results in four typical cases of trigeminal neuralgia. He believes that the peripheral lesion acts merely as an irritative focus from which the centers are continually bombarded by afferent impulses. This bombardment eventually creates an abnormal internuncial activity within the thalamus, which discharges explosively whenever a particularly strong impulse or combination of impulses arrives at the proper instant. In the fully developed syndrome of trigeminal neuralgia the slightest stimulation of the trigger point might be sufficient to detonate the pain paroxysm. But if the afferent impulses cease because the source of irritation is removed or because the messages are repeatedly interrupted, the abnormal activity within the thalamus tends to subside and the paroxysmal pain disappears. The concept is hypothetical but is consistent with the following facts: 1. Patients with symptomatic trigeminal neuralgia, in whom the pains are indistinguishable from the idiopathic type, have been cured by removal of pathologic conditions of the teeth, jaws or sinuses. 2. Myositis of facial muscles may cause typical tic douloureux, and the pain disappears when the myositis is treated. 3. Alcohol injection of the main divisions of the fifth nerve or evulsion of more peripheral portions have resulted in a cure for variable periods of time. 4. The pain attacks starting in the distribution of one division of the nerve tend to spread until they eventually involve one or both of the other divisions. 5. The alcohol-injection of the division first involved in the pain process may stop the pain in other divisions as well. 6. Repeated injections of procaine hydrochloride into trigger points may abolish the pain for variable periods of time.

Metabolic Disturbances Following Thyroidectomy.—Nafe summarizes end results of thyroidectomy as practiced by several surgeons during the last few years at the three Indiana University hospitals. These surgeons are in accord with the general tendency toward subtotal thyroidectomy; leaving a small amount of tissue, particularly in diffuse hyperplasia or exophthalmia. The surgeon need not be quite as conservative in removing hyperplastic goiters of young patients as he formerly was. The incidence of recurrences may be improved by more radical surgery, but the small percentage of recurrences does not justify a total thyroidectomy. While they have not done a total thyroidectomy, a hypothyroid state has developed rather frequently following a radical type of subtotal thyroidectomy. The major portion of these patients readjust themselves in a few months, probably by hypertrophy of the remaining gland, and only a few need thyroid extract permanently. The medical staff has stated that they prefer to treat a hypothyroid patient following surgery rather than one who still has hyperthyroidism. Sufficient thyroid tissue is left so that most patients will have a normal or slightly subnormal basal metabolic rate. They believe that by limiting surgical intervention to patients with definite thyroid disease the incidence of many indefinite symptoms that follow such intervention will be lessened. Many of these symptoms may be due to metabolic disturbances, particularly those of mild hypothyroidism. Varying degrees of hypothyroidism or myxedema occur following thyroidectomy and are frequently overlooked. Many patients are relieved by careful administration of thyroid. Severe myxedema that cannot be satisfactorily managed is occasionally an end result. It should not be precipitated intentionally by complete thyroidectomy.

Closed Plaster Method of Treatment.—During the Spanish Civil War, D'Harcourt and his associates were personally responsible for the treatment of 7,500 fracture casualties and they followed up a further 17,000 cases treated in other centers. As a result of their experience the closed plaster method of treating fractures was extended to the treatment of injuries to soft tissues in cases in which there was much loss of substance. The method was used both at an early stage (within six or eight hours of the infliction of the wound) and at a later stage when the wound had already begun to granulate. Only slight variations in technic were required for the two types of cases. The technic permits a high degree of conservative treatment. Thus, in the Battle of Ebro, a surgical unit dealt with 120 casualties, and in only five cases were amputations necessary. At the Vallcarca Hospital, Barcelona, out of 5,000 wounded treated in one year (almost exclusively fracture cases) only twenty-six secondary amputations were performed, and only few serious complications were encountered. There were twenty cases of gas gangrene, twelve of which showed vascular lesions. The number of deaths among the 5,000 was thirty-seven, fifteen due to gas gangrene, seventeen to septicemia and five to secondary hemorrhage. There were no instances of nonunion or malunion from a faulty position of the fragments, although in a number of comminuted fractures many broken pieces of bone had lost all nutrient connection. The few cases of nonunion have been in the forearm and have occurred when an extensive loss of substance was present. The cases of osteomyelitis complicating fractures have not been serious but they were persistent. The closed method of treatment did not have any definite detrimental or beneficial effect on this complicating sequel of gunshot wounds. The method reduces the period of healing, particularly that of the preliminary stage of disintegration. The strict immobilization of the wound insures a faster growth of epithelium. The treatment eliminates the painful daily dressings and thereby prevents the distribution and absorption of products of disintegration from constant handling. Proteolysis does not occur. The method does not interfere with the natural process of healing by the application of antiseptics, which, however

destructive they may be to bacteria, are also destructive to those biologic products which promote healing. Dehydration due to evaporation at the surface of large wounds is considerably reduced, and this in itself is an important factor in the healing of the wound and in the restoration of the patient's health.

Vitamins as Supplement to Sanocrysin in Arthritis.—

Secher directs attention to the importance of using large doses of vitamins A, B and C as a supplement to treatment with sanocrysin (a double thiosulfate of sodium and gold) in patients with arthritis. Many of the reactions brought about by treatment with sanocrysin are similar to those due to a deficiency of vitamins and the diet of the general population is often deficient in these. The importance of the administration of vitamins during treatment with sanocrysin is confirmed as regards thrombopenia and cutaneous reactions, in which ascorbic acid acts beneficially. Decreased tolerance of carbohydrates can be abolished in many infectious diseases by increasing the amount of ascorbic acid in the blood.

End Results of Surgical Treatment of Thyrotoxicosis.

—The clinical material on which Poate and Wyndham base this report consisted of 413 patients observed at the Royal Prince Alfred Hospital from 1925 to 1937. Only 317 were available for follow-up examination from two to fourteen years after operation. Complete freedom from symptoms was obtained in 220 (69.4 per cent), mild symptoms were present in forty-eight (15 per cent) and unsatisfactory results in forty-nine (15.4 per cent). An important lesson learned from the first group was that treatment and careful attention should not cease on discharge from the hospital. It is necessary to watch and advise each patient for about two years during the stage of readjustment. Close cooperation between physician and surgeon is of benefit to both as well as to the patient. Patients with mild symptoms are capable of doing a normal day's work. Their complaints may be due to one of the following: residual thyrotoxicosis, hypothyroidism, hypoparathyroidism, diminished cardiac efficiency, neurasthenia, or causes not associated with the original illness. With careful after-treatment, many of these patients will be included in the group of perfect cures. When mild symptoms are present hypothyroidism is commoner than persistent thyrotoxicosis. One third of the patients have this condition and are responding to thyroid administration. Two patients were successfully treated for hypoparathyroidism. The group with unsatisfactory results includes thirteen patients who died within a few days of operation, six patients who died after leaving the hospital and thirty who are still living but who cannot lead a normal life. Observations on thirty-four patients with auricular fibrillation convinced the authors that fibrillation depends more on the heart than on the thyroid gland. In 59 per cent of such cases normal rhythm was restored. It is impossible to foretell the subsequent condition of the eyes. Examination of fifty patients with pronounced preoperative exophthalmos selected at random revealed the following facts: the eyes of twenty-three patients were normal, of sixteen improved, of six not improved and of two the condition was worse.

Parrot's Pseudoparalysis in Twins.—Kuznitzky reports that a pair of twins, females, were born one month prematurely with two chorions and two amnions. The mother had latent syphilis with positive reaction. At birth the infants were free of congenital syphilis. In the third and fourth week a slight increase of temperature and on the thirty-eighth day a slightly positive Wassermann reaction were observed. At the age of 6 weeks both twins displayed suddenly the symptoms of Parrot's pseudoparalysis. They had coryza at the same time. The Wassermann reaction became decidedly positive. With antisiphilitic therapy the temperature returned to normal almost immediately and the symptoms disappeared in four weeks. The Wassermann reaction became negative in five months.

Calcification of Male Internal Genitalia. G. Parola.—p. 64.

Roentgen Irradiation of Fissured Nipple.—Astolfi reports satisfactory results from roentgen irradiations of fissured nipples in a number of cases observed at the obstetric-gynecologic clinic of Perugia. The irradiations were limited to a field measuring 6 by 8 cm. The tissues surrounding the field of irradiation were protected by dry sterile gauze. The dose for each irradiation was 80 roentgens given with a current of 120 kilowatts through a filter of 1 mm. of aluminum with 2 milliamperes at a focal distance of 23 cm. from the skin. One treatment was generally sufficient. When more than one was necessary, they were given at intervals of three days and varied from two to three in number. No other treatment was administered. The treatment proved harmless to mother and infant. It can be administered to ambulant mothers and does not interfere with lactation. Pain is attenuated and sometimes controlled a few hours after the first irradiation. The fissures are promptly epithelized.

*Thermobacterium Acidophilum in Therapeutic Experiments on Nurslings and Young Children with Dyspepsia. G. Henneberg.—p. 85.

Thermobacterium Acidophilum in Dyspepsia of Nursling.—Henneberg treated twenty-two nurslings suffering from dyspepsia, one from paratyphoid Breslau infection and one from severe eczema with thermobacterium acidophilum grown in gruels such as oatmeal containing 5 per cent dextrose and incubated for twenty-four hours at a temperature of from 34 to 40 C. The bacteria were thus given in a food which favors their growth in the hope that a further growth might be promoted in the intestine. The infants were given from 10 to 15 cc. of the mixture in from one to three doses of 5 cc. each daily. Later this quantity was increased to from one to three doses of 10 cc. daily, then to two or three doses of 20 cc. and to three doses of 25 cc. The duration of the administration varied. The total quantity of gruel varied between 30 and 2,400 cc. Injurious effects were never observed. The bacterial flora was controlled by means of Henneberg's cover glass-agar method. In eight cases the administration of Thermobacterium acidophilum was followed by a noticeable improvement in the stools and in the clinical course, although the Thermobacterium failed to be detected in large quantities. The clinical improvement was probably caused by the acidifying

effect of *Thermobacterium acidophilum* on the lactic acid contained in the food. It had not been possible to replace the prevailing disease flora by the therapeutically introduced flora. The author thinks that such a result could be expected only after longer treatment.

Value of Roentgenograms in Rectal Carcinomas. H. Rüd.—p. 126.

Trauma and Diabetes.—Troëll studied the question of somatic trauma as a causative or aggravating agent in diabetes in eight cases, with special reference to eligibility for accident insurance of persons so injured. Trauma which induced a temporary glycosuria or damaged the pancreas directly was excluded from the investigation. The traumas consisted of injuries to the feet, an elbow fracture with facial contusions, injury to the region of the liver and serious injuries to the head and the cervical vertebrae, sustained in a fall from a motorcycle. One patient, a man aged 22, had been medically examined the day before a fall from the bicycle had broken his elbow and bruised his face. No sugar had been found in the urine nor did a familial history of diabetes exist. Injury of the pancreas due to the fall was regarded as improbable. Yet several weeks later a benign diabetes developed that, at the time of writing, was some three years old, requiring insulin dosage and a special diet. In the case presenting serious head and neck injuries (65 years) no glycosuria had been discovered one and one half years after the fall. Yet six months later it was so diagnosed. In two known cases of diabetes the diabetes seems to have retarded the recovery from injuries to the feet. The author believes that severe peripheral lesions to the head, liver and extremities may be assumed to induce genuine diabetes by way of the sympathetic nervous system and, consequently, entitles to accident insurance compensation. The same economic evaluation of accidents, he thinks, should prevail in cases in which latent diabetes may be presumed because of familial involvement and in the diabetes of aged patients whose condition has either been aggravated by the trauma or the healing delayed.

*Clinical and Morphologic Considerations of Hodgkin's Disease. W. Tischendorf.—p. 98.

Pulmonary Function in Asbestosis.—According to Roemheld and his associates the relatively slight clinical symptoms of asbestosis are frequently in contrast to serious impairment of function. A divergence between the x-ray appearances and the clinical picture is likewise frequent. The degree of functional impairment which is the decisive factor in the working capacity of the patient is difficult to determine. The authors determined the oxygen consumption during the breathing of air and of oxygen in nineteen cases of asbestosis by means of Knipping's large spiograph. The tests revealed that during rest the lung could not fulfil the task of saturating the blood with oxygen. The authors also determined the respiratory frequency, depth of respiration, respiratory minute volume, vital capacity, respiratory limit and respiratory time quotient. Some of these factors were determined again after ergometrically measured exertions. Electrocardiograms, roentgenograms and thorough clinical examinations were made. There was considerable conformity between the spiographic data and the severity of the clinical picture. The spiographic examination

permits an estimation of the pathologic changes and reveals the extent of pulmonary insufficiency. Failure of pulmonary function is of great importance in asbestosis, because limitation of the respiratory reserve and deficient oxygenation of the blood are the causes of decreased working capacity at a time when their circulation is still able to meet greater demands.

Hodgkin's Disease.—Attention has been called in recent years to the similarity of Hodgkin's disease to a neoplasm. The disease frequently has its origin in a localized area at a site where large quantities of lymphatic tissue are found, such as the mediastinum, the mesenteric lymph nodes or the faucial lymphatic ring. The impression is gained that the disease begins locally and metastasizes like a malignant neoplasm. Tischendorf cites one case the clinical and roentgenologic features of which were like those of a malignant neoplasm. In another case the roentgenologic and clinical signs suggested Hodgkin's disease but the necropsy disclosed a malignant mediastinal tumor. Two cases are cited to demonstrate that the course, and anatomic picture of Hodgkin's disease may greatly resemble a malignant neoplasm. Microscopic examination of a lymph node is a distinct diagnostic advance. Lymph node or tissue puncture presents further advance in diagnosis. Experience with the method in various lymph node disorders convinced the author of its reliability. It is as reliable as lymph node biopsy provided that, besides the tissue smears, one makes histologic preparations from the punctate. Such preparations reveal the large Sternberg giant cells. Typical cases present spindle shaped fibroblasts, large epithelioid and histocytic cells, neutrophils and eosinophils. The tumor-like growth of the lymphomatous tissue with its apparent metastatic involvement and the characteristic morphologic appearances suggest a close relationship to neoplastic disease. The apparently benign course, frequently extending over eight or ten years, may be replaced by a malignant infiltrating growth in the terminal stage. During the benign course the process may simulate a lymphadenosis, but the microscopic examination discloses the true nature. A tumor-like character has been suggested also for leukemia, in which the enlargement of the lymph nodes is the result of the deposition of hematopoietic tissues whereas the glandular swellings of Hodgkin's disease are the result of the deposition of granulomatous tissue. Hodgkin's disease has been regarded as an infectious disease because of the resemblance of its lesions to ordinary granuloma and because of the febrile course. The infectious etiology has not been proved and the assumption of a tumor-like etiology is therefore justified.

Sympathetic Endocrine System and Vitamin Economy.—According to Stepp and Diehl, the endocrine glands are dependent for their function on an adequate vitamin supply. They investigated the carbohydrate metabolism from this point of view. They demonstrated in blood sugar curves following dextrose tolerance tests that it is possible to regulate abnormal sympathetic-hormonal control functions. In hypophysial insufficiency with a tendency to spontaneous hypoglycemia the blood sugar curve, following the dextrose tolerance test, could be normalized by the administration of the total vitamin B complex and of vitamin C. The formerly low apex of the curve was now higher and the abnormally deep hypoglycemic phase could be normalized. They demonstrated by means of patients with abnormal dextrose tolerance curves that the vitamin B complex has a better normalizing effect than vitamin C. The different factors of the B complex were not all equally effective; B₁ was found to be ineffective in spite of its well known relation to the carbohydrate metabolism. The simultaneous administration of riboflavin, nicotinic acid amide and vitamin

B₆ produced normalization. The authors conclude that an adequate provision of the organism with vitamins is essential for the normal functioning of the regulatory processes.

 Alkalization Therapy of Psychic Depressions. F. Hoff.—p. 237.

Diabetes Mellitus and Pernicious Anemia.—Beckert reports the simultaneous presence of pernicious anemia in nine (1 per cent) of 900 cases of diabetes. The predominant age level in the nine cases was between 30 and 50 years. Three cases were serious; six were mild. Six cases had been under observation for four years. In five cases the primary existence of diabetes could be verified, pernicious anemia having remained latent for from three to seven years. In one latent case funicular myelosis was discovered. The author did not observe that the presence of either disease led to the aggravation of the other, such as modification of the metabolism. In fact, serious cases of diabetes were observed to be accompanied with light attacks of anemia and vice versa. Only the spinal symptoms seemed to have been intensified. The theories advanced for the concurrent appearance of pernicious anemia in diabetes range from the assumption of an unrelated and fortuitous occurrence to that of gastric achylia frequently observed in diabetes. The infrequent evolution of pernicious anemia in the past is attributed by the author to the earlier decease of diabetic persons in the days when insulin was unknown. Insulin and liver extracts were found to be compatible therapies.

 Changes in Deflections of Electrocardiogram of Hyperthyroidism. W. Breu and S. Zollner.—p. 216.
 *Functional Examination of Kidneys and Intravenous Urography. K. Hutter.—p. 220.

Intravenous Urography.—Hutter maintains that the examination of the total function of the kidney is necessary whenever an intravenous urography is planned, for, if the kidneys are impaired to such an extent that an almost normal elimination of the intravenously administered contrast medium cannot be expected, not only the aim of the urography is unobtainable but there is also the danger of injuring the patient by the prolonged retention of the iodized contrast medium. Volhard's water test is used by the author for the routine examination of the renal function. He also determines residual nitrogen and the indican content of the blood serum, especially if the water test does not seem desirable. The water test was extended by combining it with tolerance tests. After a preliminary water test, the patients are given for two successive days 1,000 cc. of fluid and a prescribed diet and, in addition, 5 Gm. of sodium chloride the first day. The water test is repeated and the residual nitrogen and the indican content of the blood are determined. This makes it possible to detect (1) normally functioning kidneys and (2) kidneys with a latent impairment of the function, in which normal or almost normal values are obtained in the first test, but abnormal values after the tolerance test. Intravenous urography is contraindicated not only in the case of impairment of the total renal function but also in acute nephritis and in patients with a predisposition to thrombosis. It is indicated in phimosis, stricture of the urethra, chronically contracted or acutely infected bladder and stenosis of the ureter. Intravenous urography may not reveal stones, but it is helpful in the detection of hypotonic conditions. The psos rim symptom is of value in determining whether a hypotonic condition is due to mechanical or to dynamic causes. It is not a case of rivalry between intravenous and instrumental urography; each method has its indications. Kymographic examinations are especially valuable in estimating retroperistalsis.

 Tetanus. S. Lindgren.—p. 473.
 More Recent Views on Psychiatric Doctrine of Heredity. E. Essen-Möller.—p. 478.

Postoperative Causes of Death in Lund.—Petré finds that of the 1,265 postoperative deaths after 24,816 surgical operations from 1929 to 1938 53 per cent occurred from the basic disorder, the basic injury or a complication peculiar to the disorder or injury, and 21 per cent from a pulmonary complication, most often pneumonia or pulmonary embolism. Of the patients with fatal pneumonia 86 per cent were 55 or over, almost half were 70 or over, and 68 per cent of those with pulmonary embolism were 60 or over. In the remaining 26 per cent death was due either to wrong or to questionable indication for operation, with some of the patients for various reasons too weak for the operation performed, or to a technically faulty operation or to some special postoperative complication, not pulmonary.

- *Reticulosarcoma and Reticulo-Endotheliosarcoma in Tonsils and Rhinopharynx. S. Ohlsen and A. Jørgensen.—p. 555.

Reticulosarcomas in Tonsils and Rhinopharynx.—According to Ohlsen and Jørgensen reticulosarcomas may occur wherever there is lymphatic tissue. About 40 per cent of the cases are found in the tonsils and about 20 per cent in the rhinopharynx (Greifenstein). Ewing's sarcoma, which originates in the bone marrow, has the same histologic structure as the reticulosarcomas they describe. Ewing's sarcoma is seen in the younger age groups, the reticulosarcoma usually between the ages of 50 and 70. The clinical picture does not differ from that of other primary malignant tumors with the same localization, and as a rule macroscopic diagnosis is impossible. The growth of the tumor may be slow and the tendency to ulceration and necrosis less than in cancer. If the tumor is infected, growth may be accelerated. Reticulosarcomas are highly sensitive to roentgen rays. If there is a suspicious unilateral tonsillar tumor the authors would perform a tonsillectomy rather than wait for the results of microscopic examination of a specimen. Recognition of the tumor in the rhinopharynx is late and difficult, as the symptoms are vague and not characteristic. If diagnosis of reticulosarcoma or reticulo-endotheliosarcoma has been made by microscopic examination of a lymph node from the neck, a small tumor should be carefully looked for in the rhinopharynx. Treatment is protracted roentgen irradiation, to be instituted as early as possible. Nine cases of reticulosarcoma, all localized in one tonsil, are reported; in eight there were ulcerations, in six enlarged regional lymph nodes. In five cases the treatment was primary tonsillectomy followed by roentgen or radium treatment, in four cases roentgen treatment alone. Four patients are well after an observation period of from one and a half to five years. One case is still under treatment. One case of reticulosarcoma and one of reticulo-endotheliosarcoma in the rhinopharynx are described, both fatal.

TREATMENT OF NEPHROTIC EDEMA

ARNOLDUS GOUDSMIT JR., M.D.

PHILADELPHIA
AND

MELVIN W. BINGER, M.D.

ROCHESTER, MINN.

When the progress of medical therapy during the past twenty-five years is discussed, usually reference is made first to diabetes, second to pernicious anemia and third to various states of deficiency. Sometimes advances made in the chemotherapy and immunotherapy of infectious diseases are considered, but rarely is mention made of the great progress achieved in the treatment of patients who have nephrotic edema of moderate or extreme degree. Not long ago it was necessary for such patients to be hospitalized for many months before elimination of excessive fluids was accomplished, if it was accomplished at all. Thanks to the observations of clinicians all over the world and to better understanding of basic physiologic principles, such protracted invalidism is of comparatively rare occurrence at the present time.

In 1925, at the Mayo Clinic, dietary measures were supplemented by the administration of ammonium chloride and merbaphen (novasurol¹). Later, ammonium nitrate in combination with mersalyl (salyrgan) was the treatment of choice.² Since 1933, potassium nitrate has been preferred as the diuretic salt and, as is well known, it can be combined advantageously with mercurial diuretics.³ Experience with a case of nephrotic edema in which the disease was particularly refractory to treatment, in 1937, revealed to us the definite advantage of combining injections of solutions of acacia with the aforementioned treatment.⁴ Further experience with acacia has made it clear that many additional diuretic measures, such as the use of organic mercurial compounds, may well be dispensed with in the majority of instances.

A review⁵ of the adult patients who had nephrotic edema and who received treatment in the hospital in the last two years reveals that in fourteen instances acacia was not used. Such cases generally were of a mild character. Some patients ultimately became free from edema with nothing more than the use of a low salt diet. In all of the more extensive and resistant cases of nephrotic edema, acacia was used in treatment.

Thirty-six (90 per cent) of forty patients, on their first admission to the hospital, after treatment which included injections of solutions of acacia, were relieved of edema. Of the sixty-four patients admitted to the hospital because of nephrotic edema, fifty-five were readily relieved by treatment with or without acacia. In nine cases, measures to relieve edema were not successful before the dismissal from the hospital.

It has been noted that, in all cases in which the treatment which is to be described in this paper was not successful in mobilizing the edema, such severe anorexia and vomiting were present that neither food nor diuretic salts could be taken in adequate amounts. Except when these serious complications occurred, we have obtained satisfactory diuresis in all of the sixty-four consecutive cases. We feel confident that, with very few exceptions, the regimen which is to be outlined will prove satisfactory for adult patients who have nephrotic edema.

In order that the treatment may lead to the best possible results, it appears essential that it should be carried out in the hospital because close supervision is necessary and because it is fundamental that the amount of salt contained in the diet should be as small as possible. Also, possible complications can be handled more satisfactorily in the hospital than in the home. The patient should remain in bed until recovery is well under way. He should be weighed, preferably every morning before breakfast, and all urine should be saved and measured every twenty-four hours, in order to follow closely the effect of the therapy.

The so-called salt free diet should be prescribed. This requires (1) the use of bread and butter processed without the addition of salt, (2) the selection of food-stuffs that contain minimal amounts of sodium chloride (limitation of the amount of milk given is very important) and (3) omission of salt for flavoring purposes in cooking. In order to avoid serving too tasteless a diet, the use of moderate amounts of condiment is desirable. If patients experience difficulty in ingesting such a diet, we allow them to use a shaker filled with potassium chloride. In addition to being salt free, the diet should contain more protein than has been customarily prescribed in the average case of chronic nephritis without edema. Usually from 70 to 100 Gm. of protein each day is given. The caloric intake should be adequate to maintain the weight of the patient, and, since a considerable number of these patients are fundamentally in a condition of malnutrition, some extra calories may be allowed during the stay in the hospital. Lately we have provided extra vitamins for those patients who have been ill for a long time before hospitalization. The intake of fluid by mouth, including the volume of tea, coffee and soup, should be limited to approximately 800 cc. in twenty-four hours.

Diuretic salts are usually prescribed in the form of potassium nitrate. Most patients receive 9 Gm. daily, divided into three doses. The pills of potassium nitrate

SATURDAY, JUNE 29, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

THE IMPORTANCE OF CLINICAL INVESTIGATION

In most universities and research institutes major emphasis has been placed in recent years on basic research, which is pursued without thought of immediate practical value to man or to society. Frequently research in the fundamental medical sciences of physiology, anatomy, chemistry, biology and pathology has been enveloped in an atmosphere of profound obscurity. The material studied and the reports are expressed in terminology or in intricate mathematical formulas which make comprehension difficult. So much emphasis has been placed, in fact, on the quality of research in the laboratory as compared with research in the clinic and at the bedside that many a clinician has hesitated to express his opinions or his conclusions in relationship

to the diagnosis and treatment of disease without having first devoted some thought and consideration to research on frogs, rats, dogs, rabbits or guinea-pigs. The results obtained in studies made on animals in the laboratory are, of course, of utmost importance as a basis for the ultimate study, which must always be made with man.

In a recent address, Abraham Flexner¹ emphasized the usefulness of useless knowledge. The value of basic research as discipline certainly cannot be denied. Nevertheless, the research carefully planned and actually performed with patients in a well equipped hospital frequently offers immediate promise of benefit to mankind far exceeding such abstruse performances as are occasionally reported from the laboratories of the fundamental sciences. In his address, Mr. Flexner proclaimed that the spirit and policies which determine the course of research should be the fearless and unhampered search for truth, the unlimited cultivation of the natural curiosity of human beings within the field of science. These very words are in themselves an inspiration to the physician, who takes care of patients in the hospital and in the home, to cultivate to the utmost those fields of clinical research which are available to him.

Most laboratory scientists appreciate the easier methods of their task resulting from the ability to work with test tubes and animals. This is perhaps one reason why laboratory research is generally used by preference for fundamental investigations. Once the ground has been broken in this way, the problem can often be carried to the clinic with a much better chance of success and safety for the patient. Moreover, the methods of the laboratory must prevail in the clinic as well if clinical research is to be useful; even clinical research is most useful when it is carried on by exact methods and when the results are judged by a critical mind that rebels against superficial observations, unsound reasoning and uncritical deductions. Indeed, the clinical investigator often finds that the first approach to the problem which arises in the clinic must be made through the laboratory.

Thus there has been suggested as a typical example the work of Loeb in Addison's disease. He had been working for many years on the acid-base equivalent and the electrolyte structure of the blood. In taking care of patients with Addison's disease in the ward, the clinical condition in addisonian crises suggested to him the possibility of potassium poisoning. This led to investigation of the electrolyte pattern of these cases, which permitted the discovery of the altered potassium-sodium ratio with lowered sodium and increased potassium. This observation, in turn, suggested the use of sodium chloride in the treatment of addisonian crises. Both the experiments in the laboratory and those in

1. Flexner, Abraham: The Usefulness of Useless Knowledge, *The Field and the Work of the Squibb Institute for Medical Research* 1: 19 (Nov.) 1938.

the clinic thus led to constructive progress in the treatment of Addison's disease and to new fields of experimentation in both the laboratory and the clinic in relationship to many other problems. From an idea gained in the clinic regarding disease, the modern investigator goes back to the organic chemist, suggesting the type of synthesis needed. The products which are developed are then tested experimentally in mice, dogs and other animals so that the investigator gains a thorough knowledge of the therapeutic and pharmacologic effects. Then it is possible to take the product back to the patient, where studies are made under controlled conditions of clinical investigation.

There would seem to be need for closer approximation between the fundamental sciences and the clinic; far too often fundamental workers in chemistry, bacteriology and physiology seem to be disinterested in the application of their problems to the clinic. In fact, far too frequently they use in their discussions terms which even the scientifically trained clinician finds it difficult to understand. As Eugene F. Du Bois² has said, "Any young neophyte can introduce a new drug. It requires a man of large experience and considerable reputation to destroy an old one." The clinical investigator must be a good diagnostician; a keen, impartial observer, capable of utilizing the relatively new methods of alternate cases and blindfold tests, and of enlisting the support of the pharmacologic laboratories.

In an address, also made at the dedication of the Squibb Institute for Medical Research, Dr. Russell M. Wilder³ forcibly called attention to the need for more laboratories in which problems involving abnormal human physiology can be attacked by clinicians who have received training in investigation equivalent to that usually given to the physiologist or biochemist. He said:

Medical science, in recent decades, has developed principally in laboratories of animal physiology, and in consequence what we have learned about dogs and rats exceeds what we know about ourselves. This is partly explained by the greater ease of experimentation on lower animals, but also responsible in part is the disproportionately larger provision made for research with animals. It is only in very recent years that American universities have admitted clinicians to their faculties, and in only a few universities where this has occurred is provision made for as rigid investigation of clinical material as the physiologist conducts with dogs.

Wilder emphasized that we must learn more from man than we do learn, because much of the information obtained from other animals fails to apply to man. Striking variation is found, for example, between human diabetes and the diabetes of dogs after pancreatectomy. A difference exists in the distribution of potassium between the cells and the plasma of the blood;

explaining it may be the unlike response to treatment of patients with Addison's disease and adrenalectomized dogs. The dissimilarity of distribution of cholinergic and adrenergic nerve fibers accounts for the fact that sweating occurs in man and not in the dog and may underly species differences in susceptibility to toxins and drugs.

Research on man, however, demands even greater refinement of method, more critical judgment and more rigid control than does work with dogs or other animals. Wilder not only pleaded for scientific training of clinical investigators; he also urged that laboratories for clinical research be located when possible in hospitals which are integral parts of universities. In such environment the clinical investigator obtains guidance from laboratory workers on the one hand and criticism from clinicians on the other. He requires both—the former to hold him to the discipline of science, the latter to maintain the reliability of his clinical interpretations.

No doubt, a number of factors have been significant in developing the current relationship between laboratory and clinical research. An important influence is undoubtedly the great increase in the number of non-medical investigators: doctors of philosophy in the basic sciences who are primarily responsible for teaching in the preclinical branches. Indeed, there are many institutions in which the teachers concerned with the study of the effects of drugs in health and in disease are doctors of philosophy and pharmacology who have in their own training been without any considerable contact with actual cases of disease. The recent introduction of special emphasis on statistical studies has decreased largely the influence of many a competent scientist who emerged from the university in a previous generation and who has not been able to keep abreast of this current trend. Such men, even as heads of departments, may develop a sense of inferiority in conversing with younger men who have been especially trained in the newer technics. Nevertheless, the great field for research in medicine is today still in the clinical branches. Unfortunately, much of the material which is published as part of the contents of many medical journals represents work done in a superficial manner without proper standards, and it is likely to be subject to harsh criticism from leaders in the fundamental sciences. All these observations lead, therefore, to the eventual conclusions that proper integration of the fundamental sciences in clinical medicine and, at the same time, independent investigation in the two fields represent the primary needs of the day. On the physician rests the obligation to establish through clinical investigation all the possible practical results based on investigation in the laboratory as soon as possible in order to benefit the sick. The physician cannot always afford to wait until the fundamental discoveries have been established beyond the shadow of doubt in the

3. Wilder, Russell M.: Industrial Laboratories and Clinical Research. *The Field and the Work of the Squibb Institute for Medical Research* 1: 15 (Nov.) 1938.

laboratory. Indeed, this application of laboratory science to the bedside represents the highest type of clinical research and one which may inspire every practicing physician.

TRAINING OF PHYSICAL THERAPY TECHNICIANS

During the past fifteen years there has been a belated but gratifying growth in appreciation of the varied beneficial influences of physical therapy. Strange that one of the oldest therapeutic fields known to mankind should have waited so long to be recognized with other major factors of the medical armamentarium. As far as extension of physical therapy to the public is concerned, however, for rich and poor alike the surface has been hardly more than scratched.

In his recent address before the thirty-sixth Annual Congress on Medical Education and Licensure in Chicago, Gregg¹ remarked:

A curious phenomenon in American medicine is the deft elimination of much reference to physical therapy. Almost as those who keep their children ignorant of the facts of life, we appear to protect the American medical student from the knowledge of physical therapy, mindful, I suppose, of the abuses imputed to osteopaths and chiropractors. . . . But the effects of heat on capillary circulation, lymph flow and inflammation, and the indications and effects of massage and passive movement or of irradiation, can certainly be learned and taught as physiology without any trace of charlatanry. The current unabashed ignorance of physical therapy in this country leaves it as an excellent opportunity for development in American medicine.

These remarks are a deserved exposé of a situation which lamentably needs correction. The cults owe their origin largely, if not entirely, to the inertia and apathy with which the medical profession has regarded physical therapy. Fortunately this situation is being slowly but definitely bettered by virtue of the educational campaign now under way. Physical therapy is included officially in the curriculums of some of the leading medical schools. It has received attention and some emphasis in many others. The field constitutes a definite specialty, however, and one of the difficulties as well as one of the opportunities is the necessity of training men in this field.

In many medical centers and in many smaller communities, physicians are gradually becoming aware of the importance of applying the various measures included under physical therapy to a host of conditions. Intellectual appreciation of the therapeutic potential in this field and actual practice of its precepts are, however, two different matters. Even if the general practitioner should be equipped to carry out skilfully the various measures of physical therapy, he could himself reach only a negligible fraction of those patients, both medical and surgical, who desperately need such care. This need

can be met in a large way only by physical therapy technicians trained to use with skill and restraint those complicated measures which constitute the essential basis of physical therapy, namely heat, effleurage, massage, postural exercises, passive motion and active exercise. Fortunately the training of persons educationally qualified to enter this field, such as registered nurses or graduates in physical education, can be achieved in a relatively short time. Such qualifications do not supply that experience and skill which only time will yield, but at least they afford a direct and immediate avenue of approach to the application of physical measures. Indeed, the opportunity today for agreeable and remunerative effort, of great sociologic value, is such that young persons interested in activities within the field of medicine could well consider this vocation. Educational opportunities for training are, as indicated in a recent issue of *THE JOURNAL*,² as yet limited; but they are in process of being expanded and as the demand increases further expansion can be expected.

Direction of the activities of physical therapy technicians by qualified medical supervision is primarily important. Such qualified direction is available in only a few medical centers. Until this requirement has been filled, the medical profession and the public will be fortunate if the quota of technicians needed for a host of patients can be supplied.

The Council on Physical Therapy has often pointed out that the basis of the principles and practice of physical therapy consists in the application of heat, massage and exercise. It is still necessary to disabuse the medical mind from the thought that the field is constituted by physical apparatus. Except for refinement of application, relatively little that is new has been added, in principle, to physical therapy since the days of Hippocrates apart from the influence of the x-rays and radium. These agencies are by definition restricted to elaborate physical equipment directed by medical minds trained in these lines of effort.

Orthopedists have long since learned the value of physical therapy. Neurologists, following the lead of Weir Mitchell, now make use of this measure in a large way. Internists as a group and practitioners in general have small interest in the field and perhaps even less familiarity with it. Thousands of cases of fracture in or near joints and a vastly greater number of sufferers from arthritis are daily experiencing sharply limited motion and permanent ankylosis because of well intentioned ignorance and because of a dearth of personnel qualified to bring critically to bear even the simplest physical therapeutic measures. Precisely here many more persons adequately trained in the practice of physical therapy are needed. In respect to the more subtle practices in difficult cases the number of experienced persons is hopelessly inadequate.

Current Comment

FOURTH OF JULY

Already the American Medical Association has circularized hospitals, dispensaries and other institutions in the United States with a view to compiling within the near future a record of accidents and mortality resulting from injuries on the Fourth of July due to ignorant or too enthusiastic employment of fireworks. Many states have already adopted effective antifireworks legislation; but last year at least 5,560 people were injured, and at least thirteen died as the result of such celebrations. The majority of cases were mutilations received by boys or men who used home-made explosives, and burns of little girls whose dresses were set on fire by sparklers and fire crackers. In 1938 Pennsylvania led all other states, with six deaths from fireworks. In 1939 the records indicated that there was not one death in that state. It is about time that every state in the Union adopted effective antifireworks legislation. The contrast, in recent years, between Pennsylvania, Utah and West Virginia, which adopted such legislation, with Indiana and Maryland, which postponed legislation, should be sufficient warning to every state that the time has come to cease postponing such action.

GOVERNOR LEHMAN ADDRESSES THE MEDICAL PROFESSION

At the opening general meeting of the American Medical Association convention in New York, Governor Herbert H. Lehman made an address which brought the assemblage to its feet in applause. The moment was fraught with anxiety because of the report on the status of the war in Europe. A great orchestra of physicians had inspired the assemblage with a beautiful performance. The invocation was sympathetic and at the same time thrilling. The Governor of New York recognized the achievements of scientific medicine on behalf of mankind in the twenty-three years since the Association had previously met in New York City:

"The continued progress of any people and of civilization in general," he said, "depends upon the well-being of individual members of society" and, he continued, "there can be no doubt that the availability and utilization of adequate medical facilities and the attainment of high standards of medical care throughout the nation has become an important public consideration. Only by constant, intensive and coordinated action by the medical profession as a whole can these great needs be met. The hospital, the practicing physician and the research laboratory," he said, "are in my opinion the most important instruments in the future improvement of the well-being of the people of this nation." Bitterly he attacked the totalitarian aggression, which now threatens not only life and property but all concepts of morality, religion and thought. "Such an attack," he said, "would destroy freedom, and without freedom science cannot exist." Continuing, he said "But in those countries where freedom has disappeared science too has been beaten to earth. There science is being used not to prove truths but to distort them. It is being used not to advance human thought but to shackle it. It is being used not to make men free but to enslave them. It is being used to tear down, to maim, to kill, not to save and build. . . . Yours is a great profession. It is great in part because it is free and untrammelled. It deals not only with the bodies but with the souls of men. The spiritual

influence which you wield is as important as the purely medical. Medicine and surgery here and abroad have achieved epoch making gains on all fronts only because those who are dedicated to them could conduct and carry on their work with perfect freedom of thought and expression. . . . Science cannot possibly live and progress save in an atmosphere of complete intellectual honesty. Its very lifeblood springs from individual initiative. Its inspiration is high morality and spirituality. Science becomes impotent where freedom is lost."

The address ended with the Governor's hope that our government and our people would give all possible material help in the defense of freedom and the democratic cause. It was an address replete with re-expression of many of the ideals for which medicine has been doing its utmost throughout the years. When statesmen and leaders of our people realize that freedom of the medical profession to study and to advance are basic to every freedom of the nation, the battle for medicine will begin to be won.

DR. GEORGE WALTER MCCOY RETIRES

Dr. George Walter McCoy, for forty years on active duty in the United States Public Health Service, will retire on June 30. His contributions to the investigation of tropical diseases, his enlightened administration of the Hygienic Laboratory from 1915 through 1937 and his services to the Council on Pharmacy and Chemistry of the American Medical Association from 1915 onward are exemplifications of the vast public service which he has rendered in the field of medicine. For some twenty years also he served the advancement of medical science notably by his contribution as a powerful opponent of measures introduced into Congress by those who endeavored to inhibit scientific research through preventing the use of animals. Dr. McCoy is now director of the Department of Preventive Medicine and Public Health at the Louisiana State University School of Medicine in New Orleans. He will continue his membership on the Council. Thus he now serves still further by his ability to inspire young men with the possibilities in the field of preventive medicine. THE JOURNAL wishes for Dr. McCoy many more years of healthful life and distinguished service.

THE DECISION TO OPERATE

Dr. S. S. Goldwater, Commissioner of Hospitals of the City of New York, reports that the surgical services in one of the institutions under his supervision have adopted a rule that "all operative cases of election, excluding emergency cases, must have a record of examination by two members of the visiting staff recommending the operation." Such a rule unquestionably provides an additional safeguard for patients about to undergo elective surgery, gives added protection to the public and also adds legal and moral support to the judgment of the attending physician. The patient, the physician and the institution would all seem to be benefited by this precautionary measure. Public hospitals especially might well consider the advisability of adopting a similar rule.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

COMMITTEE ON MEDICAL PREPAREDNESS

Chairman	Ex Officio:
Dr. Irvin Abell, Louisville, Ky.,	Dr. Arthur W. Booth, Elmira, N. Y.,
Dr. Charles A. Dukes, Oakland, Calif.	Chairman Board of Trustees

	Journal of the American Medical Association

AN APPEAL FOR SERVICE

In response to a request from the Surgeon Generals of the Army, Navy and Public Health Service the American Medical Association has set its machinery in motion to secure information relative to the availability and qualifications of professional personnel for service in the federal preparedness program. Since mental and physical health is of fundamental importance in the prosecution of such a program, the doctor, with a knowledge of the measures essential to the conservation of health, the prevention and cure of disease, is in a position to make a signal contribution to its success. The medical profession, actuated by a high sense of patriotism and civic responsibility, has freely proffered its help in every emergency with which the government has been confronted. The American Medical Association has always unflinchingly placed its facilities at the disposal of the constituted authorities. During the first world war 32,000 of its members voluntarily served with the armed forces and many more thousands participated in various helpful capacities. Soon a letter and a schedule will reach you on which you may supply information necessary to enable our nation, in an emergency, to call on physicians for the services they are best equipped to render. The reply of the profession to this call for help will by its generosity and spontaneity demonstrate that medical men continue to be not unmindful of the obligations which intelligent citizenship entails and as well not only their willingness but their determination to fulfil them.

IRVIN ABELL, M.D.

Chairman Committee on Medical Preparedness.

ADDITIONAL PHYSICIANS REQUIRED FOR UNITED STATES NAVY MEDICAL CORPS

In an effort to bring up the strength of the Medical Corps of the Navy to that authorized by the Department of the Navy, an examination for entrance into the Medical Corps will be held on August 19. This examination will be held at the U. S. Naval Medical Center, Washington, D. C., and at the following naval hospitals:

Chelsea, Mass.; Brooklyn; Portsmouth, Va.; Pensacola, Fla.; San Diego, Calif.; Newport, R. I.; Philadelphia; Charleston, S. C.; Great Lakes, Ill.; Mare Island, Calif.; Puget Sound, Bremerton, Wash.

Graduates of class A medical schools who have had an internship in a civilian hospital and who are physically and professionally qualified may be commissioned in the permanent Medical Corps of the Navy as Assistant Surgeons with the rank of lieutenant (junior grade). Applicants must be less than 32 years of age at the time they receive their commissions, citizens of the United States, physically qualified for appointment as officers in the Medical Corps and must demonstrate their professional qualifications by competitive written, oral and practical examinations. The professional examination will embrace the subjects of (1) General Medicine, (2) General Surgery, (3) Obstetrics and Gynecology, and (4) Preventive Medicine and Medical Jurisprudence.

The pay and allowances for Assistant Surgeons with the rank of lieutenant (junior grade) in the Medical Corps of the Navy is \$2,699 a year if the officer has no dependents and \$3,158 a year if he has dependents.

Additional information regarding requirements may be obtained by addressing a letter to the Bureau of Medicine and Surgery, Navy Department, Washington, D. C. Applications must be completed and received in the Bureau of Medicine and Surgery prior to August 1 in order that authorization may reach the applicant in sufficient time for him to appear for examination on August 19.

BRITISH EMBASSY REGISTERING AMERICAN PHYSICIANS FOR SERVICE WITH GREAT BRITAIN

The British Embassy is registering the names of American physicians who volunteer for service in the United Kingdom in the treatment of war casualties so as to have available a list of men who may be called on if the need arises. The statement is made that these men are required mainly for the treatment of civilian casualties and that there is no question of enrolling these men in the medical services of the war forces.

ARMY MEDICAL CORPS NEEDS ADDITIONAL MEDICAL PERSONNEL

The office of the Surgeon General of the United States Army Medical Corps points out there are now authorized for the army of 280,000 an additional 1,283 Medical Reserve officers. Of this number only 363 have been procured, leaving 920 still required. Approximately 600 medical officers will be needed for the additional 95,000 men. It is stated that the War Department will authorize active duty for lieutenants to age 35 and captains to age 40. The duty will be for one year, to be renewed as required. Physicians who are anxious to obtain some military experience, and particularly young physicians who are seeking at this time an outlet for their services, will find here an opportunity to accept service for one year or for more if they desire it to obtain experience, and an income, and at the same time fulfil a patriotic duty.

ORGANIZATION SECTION

PROCEEDINGS OF THE NEW YORK SESSION

MINUTES OF THE NINETY-FIRST ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD IN NEW YORK, JUNE 10-14, 1940

HOUSE OF DELEGATES

Second Meeting—Tuesday Morning, June 11

The House of Delegates was called to order at 9:40 a. m. by the Speaker, Dr. H. H. Shoulders.

Report of Reference Committee on Credentials

Dr. J. Newton Hunsberger, Chairman, reported that 168 delegates had registered and been seated.

Roll Call

On motion of Dr. Charles W. Roberts, Georgia, seconded by Dr. J. N. Baker, Alabama, and carried, the House dispensed with the roll call.

Presentation of Minutes

Dr. H. B. Everett, Tennessee, moved that the House dispense with the reading of the minutes. The motion was seconded by Dr. John Z. Brown, Utah, and carried.

Report of Reference Committee on Medical Education

Dr. Harvey B. Stone, Chairman, presented the following report, which, on motions duly seconded and carried, was adopted section by section and as a whole:

1. Resolution on Approval of the American Foundation for Tropical Medicine, Inc.; This resolution, which was introduced by Dr. Peter Irving, New York, was not supported at the hearings of your reference committee by any one sponsoring it or having detailed knowledge of the American Foundation for Tropical Medicine, Inc. In the absence of such information, your reference committee feels unable to give its endorsement to the resolution and suggests that it be laid on the table for future action.

2. Resolutions on Specialists in Hospitals: These resolutions, which were introduced by Dr. Thomas A. McGoldrick, New York, were so phrased that your reference committee was unable to get a clear idea of their intent. No sponsor for them appeared before the committee. Your reference committee, therefore, recommends that another opportunity be offered for the sponsors of these resolutions to appear before it in support of them.

3. Report and Supplementary Report of Council on Medical Education and Hospitals: (a) Your reference committee wishes to note a clerical error on page 176, line 12, of the Handbook in which 2.1 per cent appears in the printed copy and which, it is informed, should read 97.9 per cent. A further clerical error is noted on page 180, line 10, in which the word "extramural" should be inserted following "Scottish" and preceding "medical," so that the corrected portion of the text will read "the quality of instruction in the Scottish extramural medical schools." With these textual corrections, your reference committee recommends to the House of Delegates the approval of the report of the Council on Medical Education and Hospitals.

(b) Inasmuch as paragraph two of the report of the Council on Medical Education and Hospitals contains an implication of suggested action by the House of Delegates, your reference

committee has suggested to that council that it submit to the House of Delegates a resolution embodying its ideas in this connection.

Respectfully submitted.

HARVEY B. STONE, Chairman.
ELBRIDGE J. BEST.
L. A. BUIE.
C. E. KIELY.
GEORGE BLUMER.

Report of Reference Committee on Hygiene and Public Health

Dr. Edwin S. Hamilton, Chairman, presented the following report:

Your reference committee held a hearing last night at which the proponents of resolutions referred to it were not present. Your reference committee is unable to take any definite action until the proponents of the resolutions come before it to explain the urgency of the resolutions, and it respectfully requests that the proponents of the resolutions appear at a meeting of your reference committee this afternoon immediately after the Executive Session. Unless they do come, your reference committee will have to report adversely on their resolutions.

Report of Reference Committee on Amendments to Constitution and By-Laws

Dr. David D. Scannell, Chairman, presented the following report:

1. Proposed Amendment to Article 8, Section 1, of the Constitution: Your Reference Committee on Amendments to the Constitution and By-Laws has read and approved the amendment submitted by the Judicial Council at the annual session held in St. Louis in 1939, which reads as follows:

Resolved, That the Constitution of the Association be amended by the insertion of the words "holding the title Doctor of Medicine or Bachelor of Medicine" between the words "associations" and "are" in article 8, section 1, third line.

This proposed amendment, having been submitted in 1939, is, under the provisions of the Constitution, before the House of Delegates for action at this New York session.

2. Proposed Amendment to By-Laws, Chapter VIII, Section 1: Your reference committee has heard Dr. James E. Paullin, Section on Practice of Medicine, with reference to an amendment to chapter VIII, section 1, of the By-Laws, dealing with the election of members of the Council on Medical Education and Hospitals and unanimously approves of this proposed amendment.

3. Report of Judicial Council: Your reference committee has read and approved the report of the Judicial Council with one exception. Under the heading of "Rearrangement and Rewording of the Principles of Medical Ethics" your reference committee dissents from the conclusion of the Judicial Council in this matter and recommends that the Speaker of this House appoint a committee of five to report its recommendations to the 1941 session of the House of Delegates of the American Medical Association in accordance with the resolutions introduced by the California delegation in 1939, reading as follows:

Resolved, That the Speaker of this House of Delegates appoint a committee of five Fellows of the American Medical Association to study the Principles of Medical Ethics and the form of the code of ethics of the

legal profession, having in mind the rearrangement of our Principles of Medical Ethics for continuity, the rewording for clarity, the addition of a commentary following each principle to illustrate the intent and the quoting of relating decisions of the Judicial Council; and be it further

Resolved, That this committee be directed to report its recommendations to the 1949 session of the House of Delegates of the American Medical Association.

Respectfully submitted,

DAVID D. SCANNELL, Chairman.
WILLIAM WESTON.
BARNEY J. HEIN.
CHARLES A. DUKES.
A. A. WALKER.

On motions of Dr. Scannell, duly seconded and carried, the House approved the first two sections of the report of the reference committee.

Dr. Scannell moved that the third section of the report of the reference committee, dealing with the report of the Judicial Council, be adopted, and the motion was seconded by Dr. George W. Kosmak, New York. After discussion, it was moved by Dr. A. T. McCormack, Kentucky, seconded by Dr. L. G. Christian, Michigan, and carried, that this third section of the report of the reference committee be tabled.

Dr. A. T. McCormack, Kentucky, then moved that the recommendation in the report of the Judicial Council referring to this matter be adopted, and the motion was seconded by Dr. Harvey F. Garrison, Mississippi, and carried.

The report of the reference committee, with the exception of the third section which had been tabled, was then adopted as a whole, on motion of Dr. Scannell, seconded by Dr. A. T. McCormack, Kentucky, and carried.

Article 8, section 1, of the Constitution was amended in accordance with the report of the reference committee, on motion of Dr. A. T. McCormack, Kentucky, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried.

On motion of Dr. Scannell, seconded by Dr. J. E. Paulin, Section on Practice of Medicine, and carried, chapter VIII, section 1, of the By-Laws was amended in accordance with the report of the reference committee.

Report of Reference Committee on Miscellaneous Business

Dr. Charles G. Strickland, Chairman, presented the following report, which was adopted section by section and as a whole on motions of Dr. Strickland, duly seconded and carried:

1. Resolutions on Military Service by Women Physicians: There was on Monday presented to this House of Delegates communications from the American Medical Women's Association and the Women's Medical Association of New York City, both containing a resolution of the same tenor, to wit, that the American Medical Association approach the War Department or proper authorities in order to secure military recognition and commissions for women physicians and surgeons in any defense plans.

Your reference committee takes pleasure in acknowledging the justice of the position taken in these resolutions and commends the public spirit which prompted them. It feels certain, however, that the War Department will utilize every available resource in its defense plans without regard to sex, color or creed. The Chairman of our Board of Trustees yesterday recommended the appointment of a committee to act as a coordinating committee on national defense activities. Your reference committee recommends that the communications and their contained resolutions be referred to that committee when formed for its information, consideration and action.

2. Resolutions on Care of Needy Physicians: Your reference committee feels that these resolutions, which had been presented by Dr. Charles A. Dukes, California, on instruction of the house of delegates of the California Medical Association, as written, have some objectionable features as (1) A serious study of the scope suggested will be time consuming. Unless other important work is neglected, it cannot be completed in time to report with recommendations to the 1941 House of Delegates. (2) The resolutions imply recognition of national responsibility, whereas your reference committee prefer to adhere to the

principle that each state care for its own. (3) Resolutions of this type may eventually lead to unwarranted and perhaps embarrassing expenditure.

Your reference committee recommends that the resolutions be not approved.

3. Resolution on Blood Typing for Blood Transfusion: Your reference committee recognizes the value of blood transfusion and also the importance of having donors available for emergencies. It, however, believes that both doctors and the public are already well aware of the importance of the life saving procedure and that adequate measures have, in most communities, already been taken. It is unsympathetic with the idea expressed in the resolution that blood typing and classification "may be linked with the present day project of blood testing for syphilis." It regards this resolution, as introduced by Dr. T. K. Gruber, Michigan, in behalf of the Michigan State Medical Society, as unnecessary at the present time and so recommends its disapproval.

4. Resolutions on Limiting Type and Extent of Services Offered by Laboratories of State Boards of Health: In considering these resolutions, introduced by Dr. L. W. Larson, Section on Pathology and Physiology, your reference committee recognizes the encroachments on private practice as detailed in these resolutions and sympathizes with the attempts to correct or limit them as far as such attempts do not unwittingly interfere with the control of communicable disease. As your reference committee sees it, these resolutions contemplate no further action by the American Medical Association than the recommendation to all state societies as embodied and expressed in them. Your reference committee recommends approval of these resolutions.

5. Report of Board of Trustees dealing with the Report of the Bureau of Medical Economics on Fee Schedules: Your reference committee believes that this report fairly well summarizes a subject on which it is difficult, if not impossible, to come to common accord. Its feeling is the fewer the fee schedules, the better for all concerned. It calls attention to the fact that the third paragraph of the report, made up of a single sentence, is rather involved and must be read several times for clear understanding. Your reference committee recommends approval of the report.

6. Resolution on Doctor's Day: The hearing on this resolution brought out rather sharp differences of opinion between those gentlemen who were interested enough to appear before your reference committee. Senator Bilbo's resolution, as read yesterday, has passed the Senate but has not yet been considered by the House. The difference of opinion occasioned by the appreciatory resolution introduced by Dr. Harvey F. Garrison, Mississippi, was due to the fear that Senator Bilbo had not been specific enough in limiting his appreciation to doctors of medicine and that some of the cults might take over the day as their own. What the irregulars may do no one can predict, but Senator Bilbo, in his resolution and all through the six and one half page speech that he gave, made it perfectly clear that he sought to honor doctors of medicine only and particularly the family doctor.

Your reference committee recognizes the fact that your family doctor does not particularly crave nor desire this type of laudation. Senator Bilbo's action, however, was apparently spontaneous and not instigated by the Mississippi State Medical Association or by any other medical society. It merely remains for the House of Delegates to say "Thank you" for what was evidently meant as a gracious and friendly gesture or to pass over the action unheeded. Remembering the fact that we need to retain all the friends we have in Washington, your reference committee recommends for your approval the resolution offered by Dr. Garrison.

Respectfully submitted,

CHARLES G. STRICKLAND, Chairman.
HOWARD L. SEYDLER.
HENRY C. MACATIE.
FREDERIC E. SOMMER.
HERBERT L. BRYANS.

Report of Committee on Legislative Activities

Dr. E. H. Cary, Chairman, presented the following report, which was referred to the Reference Committee on Legislation and Public Relations:

Mr. Speaker and Members of the House of Delegates:

The Committee on Legislative Activities reports that many months before the American Medical Association session in St. Louis, May 15-19, 1939, it was called to Chicago and decided on the best method of meeting the issues which would arise regarding legislation affecting the medical profession.

A plan was drawn and, with the cooperation of the members of the Board of Trustees, a number of gentlemen were selected to handle some phase of the program formulated. To each of the gentlemen was assigned a subject and he was asked to submit what he would present to a congressional committee. The response was immediate and the chairman of your committee had in hand their views when the American Medical Association met in St. Louis. At the St. Louis session a special committee was appointed by the Speaker to deal with the Wagner bill and that committee made a report which was unanimously accepted by the House of Delegates.

Following the St. Louis session of the American Medical Association, on May 25 the following gentlemen, who had been formerly asked to cooperate with our committee, were requested to come to Washington, where a full discussion was had: Drs. Frederic E. Sondern, Wingate M. Johnson, Robert L. Benson, James Milton Robb, Walter Edward Vest, Charles Gordon Heyd, R. L. Sensenich, Walter F. Donaldson, Haven Emerson and Holman Taylor. This group was joined by Drs. Olin West, Morris Fishbein, William C. Woodward, R. G. Leland, W. D. Cutter, F. S. Crockett and Edward H. Cary. We were able to agree on just what would be presented to the subcommittee of the Senate Committee on Education and Labor.

Your committee calls attention to the fact that the presentation of this material to the subcommittee of the committee of the Senate undoubtedly developed a favorable impression in Washington. Regardless of how the subcommittee utilized the material in its report there was a definite reaction through congressional halls.

Your committee has not been as active in opposing the new hospitals built for veterans, for the demands have been but a part of a general program of expansion. Regardless of whether many of them seem necessary to us, their geographic locations seem to be in line with a policy which has prevailed for the past few years.

Your committee would like to call to the attention of the medical profession that it has always been said that in a few years these hospitals would be used for domiciliary purposes. Your committee would like to suggest to the profession that, since we have not definitely destroyed the propaganda or the sentiment held in some quarters in favor of state medicine, these numerous hospitals may later offer an opportunity for exploitation in this field.

At the St. Louis session your committee stated that the Veterans' Administration in a report submitted to Congress on Jan. 30, 1939, showed that, of the 50,670 veterans under treatment at the end of 1938, 47,285 were in facilities controlled by the Veterans' Administration, 2,512 in other government hospitals and 873 in state or civil institutions.

Dr. Charles M. Griffith, medical director of the Veterans' Administration, reports as of the end of the fiscal year June 30, 1939, that they had hospital facilities in eighty-four locations in forty-five states and the District of Columbia. These had a capacity of 54,779 beds. There were, too, 16,345 beds set aside for domiciliary care in facilities under the jurisdiction of the Veterans' Administration, making a total of 71,124 beds controlled by the Administration. In addition, the Administration utilized 2,748 beds in other government hospitals.

In addition to this there is construction work in progress on forty-five major projects to provide 9,710 additional beds, some of these projects being new buildings and others being alterations and extensions.

There are 1,630 full time physicians and 4,267 nurses on duty in these field stations.

Your committee calls your attention to a notable variation in the distribution of cases in the last sixteen years:

	June 30, 1923	June 30, 1939
Neuropsychiatric	39%	57.68%
General medical and surgical.....	20%	33.12%
Tuberculous type	41%	9.20%

Dr. Griffith states that the Veterans' Administration requires that a veteran in order to be accepted for hospital treatment of a disease or injury incurred or aggravated in military or naval service must have an honorable discharge. If the applicant has had only service in peace time, he must have been discharged for disability in line of duty or be receiving pension for service-connected disability. For hospital treatment of a condition not attributable to military or naval service, the applicant must meet various requirements: length of service, character of discharge, type of disability and economic status. All of this leaves the impression that, while any veteran can be treated in the Veterans' Hospitals, there are certain difficulties which he has to overcome if his eligibility is not clearly shown.

Last year your committee made a report regarding the activities of the Farm Security Administration. It feels that it should bring to your attention some abridged statements of the Chief Medical Officer, Dr. R. C. Williams, and a digest of some of the rules and regulations under which the Farm Security Administration is operating.

Dr. Williams claims that, before any medical care plan is established in a state, an understanding is worked out with the state medical association and then agreements are worked out with the local medical societies. These agreements recognize three basic principles: (1) fee for borrower families determined by ability to pay as indicated by their farm plan; (2) free choice of participating physicians, and (3) funds set aside at beginning of the operating period in charge of a bonded trustee. The benefits included are (1) ordinary medical care (examination, diagnosis and treatment), (2) obstetric, (3) ordinary drugs, (4) emergency surgery as determined by the physician in charge, (5) emergency hospitalization and (6) many counties are adding dental service.

Families under typical agreement usually put into a pool from \$15 to \$30 annually. This varies according to benefits, size of average farm income in locality and the size of the family. A typical payment schedule for a low income county would be \$18 for a man and his wife, plus \$1 for each child. Any cooperating physician submits to trustees a monthly statement for services given to a member of the plan. These monthly bills are reviewed by a committee of physicians from the local society and each physician's pro rata share is determined if bills exceed the amount available. Bills are paid in full if there are sufficient funds. Dr. Williams stated that payments to physicians average 64 per cent of bills presented, which is said to be a higher percentage than they receive from ordinary practice among low-income farm families. The local committee which reviews the statements makes adjustments when necessary, thereby limiting misunderstanding. A county supervisor acts in a like capacity in checking on demands of families for service. In case a family is abusing the program, satisfactory adjustments can usually be made; otherwise the family is dropped from the program.

This pool plan is practical for physician and patient. The physician is available when protracted illness develops and when the family under ordinary circumstances could not afford to pay. It also distributes individual cost of medical care over many families, so that cost of severe illness to one family can be more nearly equalized. The heart of the program lies in a clear understanding by physicians and families as to what may be expected under this procedure as well as its limitations. It is a special plan for an underprivileged group of farm people. The program for medical care of the Farm Security Administration would have to have considerable modifications and changes if transferred to any other segment of the population.

One of our committee, Dr. F. S. Crockett, has been in touch for several years with the Associated Women of the American Farm Bureau Federation and the progress made has previously been reported to this House. During the past year a committee of the Indiana Farm Bureau has been appointed to study all

phases of a cash indemnity medical care plan suited to the needs of rural communities. It seems now that the desire for medical cooperation has lessened, no doubt owing to an improved economic situation.

In reference to the President's hospital construction program, at his invitation a conference was held with him on Jan. 10, 1940, to discuss his suggestions relative to hospital construction for certain depressed areas in this country. Dr. Abell's committee, including Drs. Walter F. Donaldson, Walter E. Vest, Frederic E. Sondern, Fred W. Rankin, E. H. Cary and Henry A. Luce, who unfortunately could not attend because of illness, along with Drs. West, Hayden, Leland, Cutter and representatives of the American, Protestant and Catholic Hospital Associations were present at this conference. The President made known to the group that he would have a bill drawn to construct fifty hospitals throughout the country where it could be shown that they were needed and that the people would maintain them. He also made it clear at that conference that there would be provided no subsidies for maintenance.

Since that meeting the Wagner-George bill has been introduced into the Senate. A companion bill was introduced in the House by Congressman Lea of California. At the hearing of the subcommittee of the Senate Committee on Education and Labor appeared Drs. West, Fishbein, Leland and Cutter.

Subsequently the Taft Hospital Construction plan submitted in the Senate was an interpretation largely of the attitude of the profession and, it is understood, the Wagner-George bill was redrawn utilizing several features of the Taft Amendment, but as it passed the Senate May 30 it contains some points with which the medical profession does not agree and to which its attention should be directed: 1. Definition of the term hospital in the bill should be modified to exclude health, diagnostic and treatment centers. 2. All projects to be constructed under the bill should be subject to the approval of the contemplated National Advisory Hospital Council. 3. Reference to osteopathic representation on the proposed council should be eliminated. 4. The method of selecting members of the proposed council should be given further consideration.

It is needless to say that the invasion of Norway and the military events which have occurred since this invasion have changed the situation so much that it remains to be seen whether the enactment of legislation affecting medicine will pass the present Congress.

Your committee in closing wishes to express its deep sense of loss in the death of one of its original members. Dr. C. B. Wright was intelligent and honest, faithful to his ideals, frank in expressing his judgment but at all times cooperating with his conferees for the best interest of the medical profession.

Respectfully submitted.

E. H. CARY, Chairman.
F. S. CROCKETT.
R. L. SENSENICH.
J. H. J. UPHAM.

Report of Reference Committee on Rules and Order of Business

Dr. John H. O'Shea, Chairman, presented the following report, which was adopted on motion of Dr. O'Shea, seconded by Dr. H. B. Everett, Tennessee, and carried:

Your reference committee recommends that the Executive Session of this House of Delegates be held at 2 p. m. on Tuesday, June 11. It further recommends that the House be constituted of and the attendance limited to the following: officers of the Association, members of the House of Delegates, alternate members of the House of Delegates, presidents and secretaries of constituent state associations, executive secretaries of constituent state associations, the Surgeon Generals of the United States Army, the United States Navy and the United States Public Health Service and such others as the House of Delegates may by motion admit.

Respectfully submitted.

JOHN H. O'SHEA, Chairman.
W. D. JOHNSON.
E. F. CONY.
H. S. READ.
E. H. SKINNER.

Report on Change in Name and Policy of the Council on Foods

Dr. James S. McLester, Chairman of the Council on Foods, presented the following statement, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary:

The Board of Trustees has acted favorably on the request of the Council on Foods that its name be changed to the Council on Foods and Nutrition. May I tell you briefly of a change in scope which has made advisable this change in name?

The original aim of the Council on Foods, in brief, was to promote accuracy in labeling and truthfulness in the advertising of foods. Its efforts have met with gratifying success. Manufacturers in overwhelming numbers have shown hearty cooperation, and the public has come universally to look on its seal of acceptance as an evidence of genuine merit. The success of this work, however, has made necessary a restriction in scope; the classes of food to be considered must definitely be curtailed.

This change has been accelerated by two trends: First, the Federal Food and Drug Administration has assumed the function of fixing standards and of defining foods and has stipulated that the ingredients of processed foods must be declared on the label, which makes unnecessary much of the work in which the Council originally pioneered. The Council does not, however, propose to retire from this field—far from it—but in order to avoid duplication of effort and possible conflict of authority it wishes to restrict its consideration of foods largely to the study of individual products intended for the feeding of infants, of special foods for the sick and of foods which, with a view to improving their nutritive value, have been manipulated by the addition of vitamins, minerals or other dietary essentials. This part of the work should be continued.

The second trend is seen in the epoch-making advances which are being made in the science of nutrition. Great discoveries are coming so rapidly that the public, and even the medical profession, is at times a bit bewildered. As a result, the Council finds itself exercising an important function not exercised by any other competent organization—that of assembling information and expressing authoritative opinion in the field of nutrition. It has published numerous special articles, singly and in series, with the object of clarifying this newer knowledge of nutrition and of presenting it in concrete form. It has been accorded a certain leadership and it wishes to meet this in a manner befitting a council of the American Medical Association.

With your approval, therefore, and with that of the Board of Trustees, the Council would like, while restricting its scope in one field, that of food products, greatly to broaden its work in another, that of nutrition, and accordingly to change its name to the Council on Foods and Nutrition.

Report of Reference Committee on Legislation and Public Relations

Dr. F. S. Crockett, Chairman, presented the following report, which was adopted, after discussion, section by section and as a whole, on motions of Dr. Crockett, duly seconded and carried:

1. Resolution on Military Status of and Pay to Physical Therapy Technicians: Your reference committee recommends that the Resolution on Military Status of and Pay to Physical Therapy Technicians, which had been introduced by Dr. Rollo K. Packard, Illinois, be referred to the Council on Physical Therapy for its consideration.

2. Resolution on Legislation Having to Do With the Care of the Sick: Your reference committee recommends that this resolution, introduced by Dr. John Z. Brown, Utah, be not adopted.

Your reference committee approves in principle any effort improving medical care of the indigent, but it wishes to call the attention of the House to the report of the Reference Committee on Consideration of the Wagner National Health Bill as reported at the St. Louis session last year, section 15, reading as follows: "The House of Delegates would urge the development of a mechanism for meeting the needs for expansion of preventive medical services, extension of medical care for the

indigent and the medically indigent, with local determination of needs and local control of administration, within the philosophy of the American form of government and without damage to the quality of medical service."

3. Resolution on Heroin: With reference to the resolution submitted by Dr. A. A. Herold, Louisiana, and published in the Secretary's Report, your reference committee has consulted the Bureau of Legal Medicine and Legislation and finds that a similar resolution was considered by the House of Delegates in 1927, which was referred to the Board of Trustees with a request that the Council on Pharmacy and Chemistry in conjunction with the Section on Practice of Medicine and the Section on Pharmacology and Therapeutics secure a reinvestigation of the use of heroin in the practice of medicine. In 1928 the following report was made to the House of Delegates: "This matter was referred to the Council on Pharmacy and Chemistry and that Council has submitted a report to the Board of Trustees to the effect that heroin is not considered to be therapeutically indispensable and that the Council on Pharmacy and Chemistry renews its approval of the provisions of the law prohibiting the importation of opium for the manufacture of heroin."

In view of the resolution showing renewed interest on the part of the profession, your reference committee recommends that the Board of Trustees be again requested to have the Council on Pharmacy and Chemistry review the needs for the use of heroin as a therapeutic agent.

4. Resolution on Medical Service Plans: Your reference committee recommends the approval by the House of Delegates of the resolution presented by Dr. L. G. Christian, Michigan, relative to the coordination of medical service plans. It recommends that the Board of Trustees be requested to direct the Bureau of Medical Economics to collect experience data and other pertinent information concerning prepayment medical care arrangements in order that sound practices may be developed and maintained, and to take steps looking to the coordination of medical service plans. Your reference committee also recommends that the House of Delegates reaffirm the principles pertaining to medical service plans previously adopted and urges the acceptance and application by all medical societies of the principles that prepayment group medical arrangements shall be controlled by the medical profession and that medical services be excluded from all group hospitalization plans but that, if the inclusion of special medical services are deemed necessary, the cost of such services be paid for in cash by the group hospitalization corporation directly to the insured persons.

Your reference committee suggests the importance of complete and accurate data in order that the intent of the resolution may be realized. It is recommended, therefore, that the constituent state medical associations of the states in which medical care plans are now operating or in which such plans may be formed undertake to secure the full cooperation of such medical care organizations with the Bureau of Medical Economics.

Respectfully submitted.

F. S. CROCKETT, Chairman.
CHARLES J. WHALEN.
L. G. CHRISTIAN.
WINGATE M. JOHNSON.
THOMAS A. MCGOLDRICK.

Report of Reference Committee on Sections and Section Work

Dr. Stanley H. Osborn, Chairman, presented the following report:

1. Section on Anesthesiology: Your Reference Committee on Sections and Section Work has carefully considered the content of the report of the Council on Scientific Assembly and concurs in that portion of the report which recommends the establishment of a Section on Anesthesiology. It has been evident for several years that the physicians interested in this specialty have needed a place to discuss their scientific papers. Your reference committee feels that the formation of such a section will fill a pressing need for the anesthetists and others who have an allied interest and recommends the establishment of such a section.

2. Section on Experimental Medicine: Your reference committee has carefully gone into the matter of the suggestion of the formation of a Section on Experimental Medicine. It feels that

the proposed union of the Section on Pathology and Physiology and the Section on Pharmacology and Therapeutics into a Section on Experimental Medicine would be of considerable value to these sections and bring to the new section discussion on the new fields of research in medicine. Your reference committee suggests that the Council on Scientific Assembly continue its efforts in consideration of the feasibility of combining the two sections and forming a Section on Experimental Medicine.

3. Scientific Assembly: Your reference committee has noted in the scientific program a trend toward bringing before the membership of the Association the leaders in discoveries and new developments in different branches of medicine and commends the manner in which the Council has presented these selected subjects before the members in the General Scientific Meetings particularly and has sponsored the holding of combined section meetings when subjects were of ancillary interest.

Respectfully submitted.

STANLEY H. OSBORN, Chairman.
GEORGE G. WARD.
THOMAS F. THORNTON.
SAMUEL P. MENGEL.
JOSEPH F. SMITH.

The first section of the report of the reference committee, approving the establishment of a new section to be called the Section on Anesthesiology, was adopted on motion of Dr. Osborn, seconded by Dr. Clyde L. Cummer, Section on Dermatology and Syphilology, and carried.

On motion of Dr. A. T. McCormack, Kentucky, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, this action of the House recommending the establishment of a Section on Anesthesiology was referred to the Reference Committee on Amendments to the Constitution and By-Laws for presentation of the necessary amendment to the By-Laws.

On motions of Dr. Osborn, duly seconded and carried, the second and third sections of the report of the reference committee, as well as the report of the reference committee as a whole, were adopted.

NEW BUSINESS

Resolution Approving American Museum of Health and Urging Support of Similar Museums in Other Parts of the United States

Dr. A. T. McCormack, Kentucky, introduced the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The education of the public in matters concerning medicine and the prevention of disease is of the utmost national importance in a democracy which is dedicated to the conservation and enrichment of life; and

WHEREAS, The American Museum of Health has demonstrated at the New York World's Fair that an exhibit which is scientifically authentic and dramatically presented is an effective instrument in health education; and

WHEREAS, The present administration of the city of New York under the direction of Mayor Fiorello H. La Guardia has given evidence of its broad vision in assuming the permanent establishment of this museum as part of the health program of the city of New York; therefore, be it

Resolved, That the American Medical Association at its ninety-first annual session, held in New York, approves of this museum, urges its constituent and component societies to support and promote the development of similar museums in other parts of the United States and instructs its Board of Trustees, officers and employees to give all possible support to such museums wherever they may be developed in the United States in conjunction with local medical organizations.

Resolutions on Protection of Practices of Physicians Who Might Be Called to Military Service

Dr. Carrington Williams, Virginia, presented resolutions dealing with the protection of the practices of physicians who might be called to military service, which were referred without reading to the Reference Committee on Executive Session.

Attendance at Executive Session

On motions duly made, seconded and carried, attendance at the Executive Session was granted, in addition to those indicated in the Report of the Reference Committee on Rules and Order of Business adopted by the House this morning, to full time executive secretaries of component county medical societies; Dr. W. A. Howard, past president of the Oklahoma State Medical Association; members of councils of constituent state medical

associations, and officers of component county and constituent state societies who may wish to attend.

The House recessed at 11:30 a. m., to reconvene in Executive Session at 2 p. m.

Tuesday Afternoon, June 11

The House of Delegates was called to order by the Speaker at 1:45 p. m. to hear new and unfinished business before going into executive session.

Proposed Amendment to By-Laws

Dr. J. E. Paullin, Section on Practice of Medicine, presented an amendment to chapter XV, section 1, of the By-Laws, changing number 16 to number 17 and inserting "16. Anesthesiology" after "15. Radiology," so that section 1 of chapter XV of the By-Laws shall read:

SECTION 1. Titles of Sections of Scientific Assembly.—The Scientific Assembly of the American Medical Association shall be divided into the following sections:

1. Practice of Medicine.
2. Surgery, General and Abdominal.
3. Obstetrics and Gynecology.
4. Ophthalmology.
5. Laryngology, Otology and Rhinology.
6. Pediatrics.
7. Pharmacology and Therapeutics.
8. Pathology and Physiology.
9. Nervous and Mental Diseases.
10. Dermatology and Syphilology.
11. Preventive and Industrial Medicine and Public Health.
12. Urology.
13. Orthopedic Surgery.
14. Gastro-Enterology and Proctology.
15. Radiology.
16. Anesthesiology.
17. Miscellaneous Topics. (As amended, 1932, 1937, 1940.)

This proposed amendment was referred to the Reference Committee on Amendments to the Constitution and By-Laws.

Report of Judicial Council

Dr. George Edward Follansbee, Chairman, presented the following supplementary report of the Judicial Council, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws:

1. Principles of Medical Ethics Pertaining to Patents and Perquisites: In its primary annual report this year the Judicial Council in its consideration of the subject of patents stated: "The Judicial Council has given extended consideration as to how to maintain the principle of benefit to humanity as the prime consideration in our Principles of Medical Ethics and at the same time to satisfy the reasonable demand that a physician, having given time and money for the benefit of humanity, shall be permitted to protect himself against exploitation by others and to receive reimbursement for his expenditure." The Council is now obliged to admit its failure to find a solution.

Its study developed certain patentable features not now included but which should be, and it believes the wording of the section can be improved. The Council therefore recommends that The Principles of Medical Ethics, chapter III, article 1, section 5, be amended to read "It is unprofessional to receive remuneration from patents or copyrights on surgical instruments, appliances, medicines, foods, methods or procedures. It is equally unprofessional, by ownership or control of patents or copyrights, either to retard or to inhibit research or to restrict the benefit to patients or to the public to be derived therefrom. It is unprofessional to accept rebates on prescriptions or appliances, or perquisites from attendants who aid in the care of patients."

2. Membership in the American Medical Association: As stated in the report of the Secretary and also in the report of the Judicial Council, there are divergences of qualifications for membership in component county and constituent state associations which operate to advantage in representation in this House

qualifications for membership in their component county societies are broad and inclusive as against those state associations that are more restrictive. Some component county societies admit osteopaths as such, others admit osteopaths who are licensed by the state to practice medicine and still others deny membership to any osteopath. Some societies require licensure by the state to practice medicine, while others do not. The members of the American Medical Association are the members of the component county medical societies whose names are certified to the American Medical Association by the constituent state medical associations.

The component county medical societies have various classifications of members. The Judicial Council knows of at least eight; viz., regular, active, associate, affiliate, honorary, retired, intern and nonresident. Some constituent state associations report only regular or active members, some include other classes and at least one reports all classes of membership in the component county societies for membership in the American Medical Association.

Such a wide diversity of qualifications for admittance to the component county medical societies, such a variety of classification of membership and such irregularity of reporting to the American Medical Association can hardly avoid violation of the democratic principle of equal representation and opportunity for all.

The American Medical Association has no power of compulsion to require any component county medical society or constituent state medical association to do in respect to its membership anything the county or state organizations decline to do on request. It can govern only its own membership, but compulsion should not be needed. In the interest of all, the constituent associations should be capable of and willing to bring about uniformity out of the present chaotic situation.

In its study and review of membership in organized medicine the Judicial Council has noted the diversity of activities which have claimed the training and knowledge of the medical graduate and have been absorbing him rapidly from the field of his primary object in obtaining that education and knowledge—the care of the sick. That primary object still activates the majority of medical graduates but greater and greater numbers of them are being attracted and absorbed into industry, teaching, research and other activities removed from medical practice and its sympathies and ideals. They live in a different world. Some belong to organized medicine, many do not. The question arises as to whether they should be in an organization such as ours or whether they belong in organizations in the line of their activities. Almost one hundred years ago, when the American Medical Association was formed, with few exceptions a doctor was a doctor whose only interest in life was the care of suffering humanity. That condition remained for many years and our organization has grown in number along with the population. But times have changed and many graduates in medicine have found interest and occupation in fields some of which are far removed from the needs, purposes and ideals which created this organization and produced its astounding growth in members and in service to humanity. The question arises: Are we growing out of our real reason for existence—the benefit of humanity—into something else? The Council believes that the evidence, slight as it may be, is sufficient to sound a note of warning. Thought should be given as to whether the time has come when we should restrict membership in this body to those physicians interested enough in the science of medicine and its practice to have taken at some time the trouble to become licensed to practice medicine. The Judicial Council recommends that only Doctors of Medicine licensed to practice medicine and whose licenses are registered in the county or state in which they make application be accepted for full membership in the American Medical Association.

Respectfully submitted.

GEORGE EDWARD FOLLANSBEE, Chairman.

Report of Reference Committee on Reports of Officers

Dr. Walter E. Vest, Chairman, presented a report which was amended to read as follows:

ADDRESS OF THE SPEAKER

1. Your reference committee would stress especially the point that the Speaker that scientific achievement, unless based

on sound ethical principles and balanced by moral character in its proponents, may be far more destructive than constructive and that the greatness of the organized medical profession consists in its exemplification of these principles in its aims, endeavors and achievements.

Your reference committee would stress also the point made by the Speaker that the American Medical Association is a true democracy in that it is the only medical organization including all segments of the profession, it promotes freedom for all, including both profession and laity, and its House of Delegates affords an open forum to which all questions touching on health and medicine may be brought for discussion and decision.

ADDRESS OF PRESIDENT

2. Your reference committee would especially commend the suggestion of the President of the American Medical Association that further effort be made in educating the profession generally as to the activities and accomplishments of the headquarters of the American Medical Association. Certainly all the state organizations and the larger county societies could have such efforts made, and the more generally the work at headquarters is understood and appreciated, the greater is the solidarity of the profession generally. Your reference committee is so impressed with the weight of the duties of the presidency of the American Medical Association as to venture the suggestion that consideration be given to the employment of a man at headquarters who could act in the capacity of field agent and aid in educating not only the medical profession but also the laity and especially the other professions as well.

3. Your reference committee would urge on this House of Delegates the absolute necessity of following the advice of the President of our Association in unstinting support of the federal government in the campaign for preparedness in the present chaotic state of a world in which right and reason have been cast to the winds and only brute force is recognized and heeded.

4. Your reference committee advocates unwavering support of the demand of the President of our Association for the continued freedom of medicine from political domination. It admits the necessity, however, of the surrender of a measure of freedom under the stress of military necessity but demands that provision be made for the return of full freedom when the military emergency shall have passed.

5. Your reference committee commends especially the comments of the President of our Association on the basic causes of disease inherent in poor housing, poor diet, poor raiment and the lack of observance of the golden rule in all walks of life. Governmental efforts at remedying these basal defects in our American society of today and frank recognition by government of the common sense principle that the medical profession is the only segment of our population equipped by education and training to initiate, advise on and carry through a satisfactory national health program would go far toward ameliorating our health and medical problems.

ADDRESS OF PRESIDENT-ELECT

6. Your reference committee would emphasize the danger pointed out by our President-Elect not only to medicine but to society in general of the world chaos of today. It would stress particularly the loss of the sense of responsibility of the individual for his own welfare and that of his dependents and the gradual trend toward the ideology of the totalitarian state—a philosophy incompatible with a free democracy and the greatest measure of individual freedom. The organized medical profession, by its traditional freedom and democracy, not only is able to point the way to a restoration of individual and community self reliance and stability but is definitely obligated to do so.

7. Your reference committee approves the support, voiced by our President-Elect, of the plan of the President of the United States for the construction of small hospitals by using federal funds in communities where actual need can be shown, provided there is strict adherence to the President's plan for construction only where actual need can be shown, and then only where the local governmental unit can demonstrate its ability and willingness to maintain the institution when built. Your reference committee feels that it is a duty of the medical profession to

emphasize to local governmental bodies applying for hospital construction the actual cost of maintenance of such institutions.

8. Your reference committee especially commends to this House of Delegates the suggestion offered by our President-Elect that it is a responsibility of the medical profession to initiate programs to meet community needs for medical and health betterment. Moreover, the medical profession not only should lead in health movements but should engage in active support of all programs for community betterment and should guide the health and medical phases of all such activities.

9. Your reference committee would urge on each member of this House of Delegates the necessity for careful study of the duties of its members as outlined by our President-Elect. We are the liaison officers between the personnel we represent and the national organization and should function as such. We should know every phase of the needs of our constituencies as well as the program and work of the national organization and should disseminate this knowledge to layman and physician alike. Your reference committee commends also his remarks on the responsibilities and duties of this House of Delegates as an organized body.

10. Your reference committee commends further the historical sketch given by our President-Elect of the efforts which have been made by the American Medical Association to secure the unification and integration of the health activities of the federal government. Even though such efforts extending over almost three quarters of a century have been unavailing, we should continue them until success crowns our efforts, for nothing is ever settled until it is settled right.

11. In closing, your reference committee would commend to the House of Delegates and to the profession generally the suggestion of our President-Elect that "the medical profession should go along with the government as far as possible for the common good without sacrificing its individual interests in the care of the sick and its collective interests in the prevention of disease." It is the opinion of your reference committee that government, the people and the medical profession will all fare better if government and the profession sit down around the conference table and agree on health plans and activities that can be mutually followed.

Respectfully submitted.

WALTER E. VEST, Chairman.
WILLIAM R. BROOKSHIER.
JAMES Q. GRAVES.
WALTER B. MARTIN.
ANDREW F. MCBRIDE.

The report of the reference committee was adopted, as amended, section by section and as a whole, on motions of Dr. Vest, duly seconded and carried after discussion.

Report of Reference Committee on Hygiene and Public Health

Dr. E. S. Hamilton, Chairman, presented the following report, which was adopted on motion of Dr. Hamilton, seconded by Dr. Felix J. Underwood, Mississippi, and carried:

Your reference committee recommends the passage of the Resolutions on Venereal Disease Program, which had been introduced by Dr. J. N. Baker, Alabama.

Respectfully submitted.

E. S. HAMILTON, Chairman.
FELIX J. UNDERWOOD.
W. F. DRAPER.
KARL S. J. HOHLEN.
CLYDE L. CUMMER.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. Ben R. McClellan, Chairman, presented the following report, which, on motion of Dr. McClellan, duly seconded and carried, was adopted by a rising vote, there being no negative votes:

REPORT OF THE SECRETARY

Your reference committee congratulates the Secretary and the Association in general on the gratifying increase in membership and Fellowship during the last year. It is a source

of satisfaction to observe the increased interest in the affairs of organized medicine displayed by all members of component county medical societies and constituent state medical associations.

In regard to field work, your reference committee believes that ways and means should be devised to lighten the burden now being carried by the President, President-Elect and general officers of the Association, and suggests that the number of those charged with this responsibility be augmented.

Your reference committee expresses appreciation of the valuable service rendered by our beloved Secretary and realizes that his brief report in no way discloses the tremendous amount of work and effort that he expends in the performance of his duties.

REPORT OF BOARD OF TRUSTEES

Your reference committee is impressed with the fact that during the last year there was an expenditure of nearly half a million dollars in carrying on the work of the various councils, bureaus and departments of the Association alone. The average member does not appreciate the expense involved in carrying out successfully the extensive activities of the Association. In view of the fact that demands on the treasury are increasing and returns on investments are decreasing to a serious extent, your reference committee emphatically suggests that any proposed activity, program or study requiring the expenditure of funds be given the most careful consideration. It is gratifying to note the ever increasing popularity of *THE JOURNAL*, which is due in the main to the excellence of its many departments.

The work in press relations deserves commendation. Wide distribution and control of information concerning matters of health among the newspapers of the country by means of the *AMERICAN MEDICAL ASSOCIATION NEWS* has been of great value in disseminating authentic information and improving the status of medicine in the eyes of the public.

Your reference committee believes that the financial loss sustained in the publication of the special journals is more than balanced by the services rendered subscribers in making available specialized information. This is a contribution advancing scientific medicine and aiming at improved standards of practice. Your reference committee therefore urges increased support by the members of our Association.

The determination on the part of the Board of Trustees to use every effort and means to defend the American Medical Association against the charges that it is guilty of conspiracy and of violating federal antitrust laws should receive the whole-hearted endorsement of the House of Delegates.

The importance of the work of the Council on Pharmacy and Chemistry, which has been carried on for a period of thirty-five years, cannot be overemphasized. Those members who have given so unselfishly of their time and effort, such as Dr. Hatcher and Dr. Sollmann, are deserving of the greatest praise.

The efforts of the Council on Foods to establish a rational basis in the use of vitamins and in the broader aspects of nutritional problems merits our commendation. It is to be hoped that some of its policing duties in regard to the merits of various foods will be taken over by federal bureaus, where they belong.

Time will not permit an adequate analysis of the work of the Council on Physical Therapy and the Council on Industrial Health. Your reference committee recommends, however, that members of the House familiarize themselves with the activities of these bodies. The value of the Council on Physical Therapy is becoming annually more apparent. Your reference committee notes with approval the very complete program it has initiated and developed. Standardization of apparatus and procedure, well planned research and evaluation of experience in the use of various modalities will do much to safeguard the patient and the profession in the field of physical therapy.

The Bureau of Health Education deserves great credit for carrying on its many activities. Special commendation should be given for its contact with government and lay organizations. Your reference committee believes that the efforts of this bureau should be endorsed and expanded.

The retirement of Dr. William C. Woodward, who directed the activities of the Bureau of Legal Medicine and Legislation

for eighteen years, deserves the attention of the House of Delegates. We are all familiar with the great work he has done in behalf of American medicine and your reference committee believes that it voices the sentiments of the House when it conveys to him a special message of appreciation and the wish that he may continue to enjoy good health for many years to come.

Your reference committee suggests careful study of the valuable report of the Bureau of Medical Economics. The appropriation by hospitals of the services of the physician both clinical and laboratory is to be deplored and if allowed to continue and develop will threaten the future of medicine and endanger the welfare of the public. It is high time that the medical profession through its state and county societies assert its rights in no uncertain terms regarding these abuses. The ten principles adopted by the House of Delegates in 1937 and revised and reaffirmed in 1938 provide that hospital service insurance should not include any type of medical care and your reference committee again stresses the importance of this declaration.

Your reference committee respectfully suggests that some agency of the American Medical Association study the indemnity plans offered by old line insurance companies to the end that the physician and the insurance company may arrive at a better understanding of their common interests.

The responsibility of the Bureau of Investigation has been greatly increased since the adoption of the Wheeler-Lea Amendment to the Federal Trade Commission Act. Your reference committee notes with satisfaction the Bureau's contacts with the lay public.

Your reference committee congratulates the Bureau of Exhibits on the high quality of the exhibits at our annual sessions as well as of those displayed at the New York and San Francisco fairs.

In conclusion, your reference committee marvels at the untiring efforts and record of achievement of your Board of Trustees.

Respectfully submitted.

BEN R. McCLELLAN, Chairman.
W. F. BRAASCH.
JOHN M. BIRNIE.
JOHN H. FITZGERALD.

Attendance at Executive Session

On motions, duly made, seconded and carried, attendance at the Executive Session was granted, in addition to those previously indicated, to Drs. Ross A. Woolsey, past president of the Missouri State Medical Association; Grady N. Coker, past president of the Medical Association of Georgia; Tom B. Throckmorton, who previously served in the House of Delegates; William H. Ross, past president of the Medical Society of the State of New York; J. Milton Robb, past president of the Michigan State Medical Society, and N. S. Davis III, president of the Chicago Medical Society.

Executive Session—Tuesday Afternoon, June 11

The Sergeants-at-Arms polled the House, after which, on motion of Dr. R. W. Fouts, Vice Speaker, duly seconded and carried, the House went into Executive Session at 2 p. m., with Dr. H. H. Shoulders, Speaker, presiding.

Report of Reference Committee on Executive Session

Dr. Edward R. Cunniffe, Chairman, presented the following report, which was adopted, after discussion, section by section and as a whole, on motions of Dr. Cunniffe, duly seconded and carried:

1. Resolutions Authorizing Organization of a Committee on Medical Preparedness: Your reference committee is proud to see the patriotic tradition of the medical profession so well exemplified in these spontaneous and thorough resolutions of our Board of Trustees. It is in strict accord with the history and traditions of the American Medical Association, which has always been foremost in offering all its facilities and services to our government in times of stress or emergency. Your reference

committee has learned that through an unintentional omission the name of the Chairman of the Board of Trustees was not included among the ex officio members and the method of appointing the members from the House was not specified.

Your reference committee feels that the Chairman of the Board of Trustees should be included among the ex officio members and that the members selected from the House of Delegates should be appointed by the Speaker of the House of Delegates.

Your reference committee wholeheartedly approves these resolutions and moves their adoption with the inclusion of these two changes.

2. Procurement of Professional Personnel for Medical Corps of Army in Event of a National Emergency: Your reference committee has carefully considered this plan presented by Dr. George C. Dunham and is pleased to see such evidence of a desire for cooperation. It endorses the principles advocated but feels that the details should best be left to the committee established by the resolutions of the Board of Trustees.

Your reference committee feels that in the choice of personnel every physician capable of rendering service should be given opportunity to offer such service to our government; that in the selection of personnel for special services there should be no arbitrary selection on the basis of organization or bodies thus far still in a developmental stage, but rather that membership in well recognized scientific specialty organizations, hospital appointments and similar qualifications should also be considered for this purpose.

Your reference committee therefore recommends that the thanks of the House be extended to Dr. Dunham and that the general principles of his plan be endorsed.

3. Resolution on Military Activities: The following resolution, presented by Dr. George R. Dillinger, Indiana, was considered by your reference committee:

WHEREAS, Worldwide social change, instability and a state of war exist among other nations; and

WHEREAS, These conditions threaten our nation and our American ideals; and

WHEREAS, The American Medical Association believes that national unity and a prepared national defense offer the best manner for defending our nation and the American way of living against these conditions; therefore be it

Resolved, That the American Medical Association constitute and empower a committee to act in liaison with proper military and civil authorities and veterans' organizations to make a complete study and prepare a detailed program for medical coordination and preparedness in the event of M-day (mobilization-day) becoming a reality, to the end that in such event an unhurried and effective program will be established supplying first the medical needs of the military; second, the proper medical care at home during a military emergency.

Your reference committee wishes to congratulate the Indiana State Medical Association on its early consideration of medical defense and to recognize the value of its committee, which is already functioning and will be of great aid to the American Medical Association committee. It recommends the approval of the principles of the resolution.

4. Resolutions on Protection of Practices of Physicians Who Might Be Called to Military Service: Your reference committee had before it the following resolutions introduced by Dr. Carrington Williams, Virginia:

WHEREAS, Military preparations in the United States will require the use of a large number of members of the American Medical Association as officers in the Medical Corps of the Army and of the Navy; and

WHEREAS, The average physician has responsibilities and financial obligations out of proportion to the pay of these officers; and

WHEREAS, The medical profession has always recognized the principle of protecting the interests of fellow physicians; therefore be it

Resolved, That the House of Delegates recommends to the constituent state and component county societies that they work out plans whereby the practice of physicians absent from their homes in the service of our military and naval forces both in periods of training and in actual service be protected and whereby some financial return from such practice be secured for the physician so absent in the service; and be it further

Resolved, That the House of Delegates urges the component societies to make every effort to work out such plans in the shortest possible time as a part of the contribution of this Association to military preparedness; and be it further

Resolved, That the Secretary be requested to forward copies of these resolutions to the presidents of the constituent state and component county societies.

Your reference committee, having carefully considered these resolutions, wishes to endorse in principle the ideas postulated and to urge further that the constituent state and component county societies be authorized to set up committees to work out methods to protect both the financial and the professional interests of physicians who may be engaged in either temporary or continuous military service.

5. Resolution Concerning Certain Objectionable Practices of Insurance Companies: Your reference committee considered the following resolution introduced by Dr. John H. Fitzgibbon, Oregon, and adopted by the Council of the Oregon State Medical Society:

WHEREAS, Certain insurance companies that write medical indemnity insurance, or medical expense insurance or health and accident insurance or insurance providing for compensation and medical aid benefits to workmen injured in the course of their employment have established the practice of demanding from physicians reports of diagnosis and treatment without the authorization of the assured; and

WHEREAS, Many of these companies also attempt to fix the fee for the physicians' services and often attempt to apply the fee schedule of the state agency administering the workman's compensation law, even though the physician has no contractual or other relationship with the insurance company involved; and

WHEREAS, The fee schedule of the agency administering the various workman's compensation laws has been established in cooperation with representatives of the medical profession and is based on a generous discount from customary fees offered by the medical profession to a nonprofit state agency as a gratuitous contribution to the welfare of their state and community; and

WHEREAS, There is no justification for commercial organizations operating for profit to apply such fee schedules in order to make a profit for themselves; and

WHEREAS, These practices are not confined to Oregon but are national in their scope; now therefore, be it

Resolved, By the Council of the Oregon State Medical Society, (1) That the practices of such insurance companies in demanding from physicians reports of diagnosis and treatment without the authorization of the assured and in so fixing the fee for the physician's services even though the physician has no contractual or other relationship with the company involved are hereby declared to be contrary to the best interests of the public and the medical profession; (2) That a copy of this resolution be sent to the Secretary of the American Medical Association for the attention of the House of Delegates of that Association; and (3) That the delegate from Oregon to the coming session of the House of Delegates of that Association be furnished with a copy of this resolution and that he be asked to have this matter brought to the attention of said House of Delegates.

Recognizing the problems arising from the conditions set forth in this resolution and recognizing injustices connected therewith, your reference committee recommends that the House of Delegates go on record as disapproving practices by insurance companies tending to bind the profession to accept voluntarily fee schedules adopted for the purpose of providing medical service insurance to groups of limited income or fee schedules accepted from the operations of workman's compensation acts.

Respectfully submitted.

Report of the Committee to Confer and Consult with Proper Federal Representatives

In the absence of Dr. Irvin Abell, Chairman of this committee, the Secretary, at the request of the House, read the following report of the committee:

To the House of Delegates, American Medical Association:

Under date of Dec. 29, 1939, the President of the United States, through his secretary, Edwin M. Watson, extended an invitation to the committee appointed by the House of Delegates of the American Medical Association to confer with federal representatives relative to the proposed National Health Program to meet again with him on January 10 to discuss a plan for the construction of hospitals with federal funds, first suggested by him on December 21. Representing the American Medical Association were the following members of the original committee: Drs. E. H. Cary, Walter F. Donald-

son, Frederic E. Sondern, Walter E. Vest, Fred W. Rankin and Irvin Abell. Dr. Austin A. Hayden was appointed by the Speaker of the House, Dr. H. H. Shoulders, to fill the vacancy created by the illness of Dr. Henry A. Luce. Also in attendance representing the Association were Drs. Olin West, Secretary, R. G. Leland of the Bureau of Medical Economics and W. D. Cutter of the Council on Medical Education and Hospitals. In attendance at the conference were representatives of the American, Catholic and Protestant hospital associations in the persons of Drs. Fred Carter and Bert W. Caldwell, Monsignor H. M. Griffin, Rev. Alphonse Schwitalla and Rev. Paul R. Zwilling. The federal representatives included Surgeon General Thomas Parran and Dr. Joseph Mountain of the U. S. Public Health Service and Surgeon General Ross T. McIntire of the Navy. Previous to the conference with the President the representatives of the medical profession and the hospital associations met and discussed the situation in the light of such knowledge as had become available through the letter of the secretary to the President, the press release of the latter on Dec. 21, 1939, and the letter of Surgeon General Parran to state health officers. The following memorandum of principles was adopted without dissent:

Following a discussion participated in by the committee representing the American, the Catholic and the Protestant hospital associations and the American Medical Association, the following points are presented as representing their joint conclusions:

1. Hospitals to be built only where need for same can be shown. Advisory consultation in the determination of such need to be given by the state medical and hospital associations, the state health department and the county judges or officials of the counties in which such hospital service is proposed.
 2. Size of hospital to be commensurate with the needs of the community and the ability of the latter to support it.
 3. Means for the maintenance and upkeep of such hospitals to rank in importance equal to that of construction.
 4. Since the important objective of the program is the service it can render, hospital construction and administration, equipment, staff and personnel to meet the standards which the American Medical Association, the American College of Surgeons and the hospital associations regard as minimal for rendering such service in the various localities. Where needed, since highly specialized facilities and personnel cannot be made available in all places, affiliation with larger hospitals or hospital centers to be had to the end that highly specialized services, diagnostic and therapeutic, be made available to all.
 5. Maintenance of a standard of professional and hospital service to keep it efficient and to prove attractive to qualified men and women as a career.
 6. Utilization of existing facilities where possible, the program under no circumstances to be allowed to develop into competition with the voluntary hospitals but rather to foster cooperation between the two groups.
 7. Many smaller communities can be better served by the utilization of bed vacancies in available existing institutions than by the construction of new hospitals, transportation and per diem expense to be borne by federal, state and/or county funds. Where state and/or county funds cannot be provided, such expense to be met by federal grants-in-aid to, and to be dispensed by, local agencies.
- Ambulance service and good roads will permit this type of service to operate safely, efficiently and economically in communities not financially able to support a hospital.

The conference held in the White House at 11 a. m. Jan. 10, 1940, was opened by the President, who discussed in a general way the difficulties, financial and legislative, of providing a national health service such as that proposed in the National Health Program. The impression gained from the President's statements is that the cash involved will, temporarily at least, inhibit the administration from fostering such legislation at the present session of the Congress. The President proposed the construction of hospitals as an experiment, the plan being somewhat as follows: for the present year to construct fifty 100 bed hospitals in communities where such facilities do not now exist. The buildings are to be fire proof, one story in height and of the poured concrete type. By using the models and molds of uniform size and similarity and employing WPA labor, it is estimated that a 100 bed hospital can be constructed and equipped at a cost not to exceed \$150,000, or \$1,500 a bed. It was stated that ten million dollars is available for the first year of the program. When asked if the program would be a continued one, the reply was that the proposed project is an experiment and, if one year's operation proved its success, another fifty hospitals could be considered as a program for another year. Requests for location of hospitals are to come from local communities, which must at the same time furnish

assurance of their ability to maintain and operate them. After construction the hospitals are to be given to the local community, the government retaining title to the properties. The personnel of the staff is to be drawn from the local profession and an effort made to affiliate the newly constructed hospitals with well established nearby institutions, with the view of stimulating and maintaining standards of professional service. The United States Public Health Service will have the duty of inspection with relation to maintenance of standards, executive, administrative and professional. The President expressed the wish that the public may have access to these hospitals for consultative and diagnostic as well as therapeutic service. It was stated that the program in no wise contemplated competition with already existing hospitals, realizing that in isolated instances such conflict will occur. When asked if vacant beds in existing institutions could be utilized for the hospitalization of the indigent, the per diem cost being met by federal funds, the President said that such a plan of federal subsidy would result in an expansion throughout the country so great as to entail a cost that could not be met, concluding with the significant statement that the primary responsibility for the medical care of the indigent rests on the state and the local community. The conference was friendly throughout and the principles of the plan proposed offered nothing of serious moment to which objection was made; its practicability was not under discussion. At the conclusion of the conference a copy of the memorandum of principles listed and a selection of brochures from the files of the American Medical Association assembled by Drs. Leland and Cutter dealing with various hospital problems were left with the President.

Following the conference a meeting of the representatives of the medical profession and the hospital associations was held at which Surgeon General Parran was present. He presented for inspection the hospital blue print prepared by the architect of the WPA engineering department. To those familiar with hospital arrangement it was apparent that alterations were necessary to obtain efficient service. Surgeon General Parran explained the method of selection of hospital sites as follows: Requests for hospitals are to be made by local communities with the concurrence of the local profession, the health or welfare department and responsible local officials, such requests to be considered by the United States Public Health Service and an advisory group of six physicians selected from the country at large, their qualifications to be familiarity with hospital problems. On Sunday, January 21, Surgeon General Parran called the chairman of this committee on the long distance phone relative to the form of the material regarding the hospital program to be presented to the Congress by the President on his birthday, January 30. Dr. Parran stated that he wished the members of our committee to be familiar with the wording and the format of the material, evidently desiring to avoid the criticism made regarding the formulation and introduction of the Wagner bill. He stated that, in order to avoid the possibility of press publicity previous to the presentation by the President, it was further desired that no copies of the tentative program be sent to the members of the American Medical Association and the hospital association committees. I requested that a digest of the material be sent to me, to which he replied that he preferred reading to me over the telephone the entire outline. I presume this to have covered between two and three typewritten pages and as I listened to its reading I detected nothing other than that which had been presented to us in Washington both by the President and later by Dr. Parran at our conference at the Mayflower Hotel. The suggestion is made that the sum of ten million dollars be appropriated for this year and an equal sum as may be needed each year hereafter, the site of the hospitals to be determined by application of the individual communities with assurance of ability to maintain hospitals when constructed; investigation then to be carried out by the United States Public Health Service, with confirmation or rejection by an advisory board of six members to be selected from the country at large and to consist of men more or less familiar with the hospital situation; the hospitals to be manned by local personnel and to be inspected by the United States Public Health Service with a view to the maintenance of standards and efficiency, and the building of the hospitals to be carried out by

the Works Projects Administration and to be of the approximate cost mentioned in our conference.

The Wagner-George hospital construction bill, S. 3230, seeking to make legally active the President's program, was introduced into the Senate and referred to the Senate Committee on Education and Labor. Representatives of the American Medical Association appeared before a subcommittee of this committee and expressed the views of the Association relative to the matter under discussion. The committee retained some of the provisions of the Wagner-George bill, inserted some of the provisions of the Taft plan and added some provisions of its own. Some of the suggestions advocated by representatives of the American Medical Association and of the hospital associations are found in the bill reported by the Senate Committee on Education and Labor to the Senate on April 30. An analysis of this bill is to be found in the Organization Section of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, May 11, 1940, pages 1927 and 1928.

Respectfully submitted.

IRVIN ABELL, Chairman.

After discussion, the report of the committee was referred to the Reference Committee on Legislation and Public Relations.

Dr. R. W. Fouts, Vice Speaker, moved that the House adjourn from executive session and immediately convene in regular session. The motion was seconded by Dr. Walter E. Vest, West Virginia, and carried.

The Executive Session adjourned at 4 p. m.

Tuesday Afternoon—(Continued)

The House reconvened in regular session at 4 p. m. with Dr. H. H. Shoulders, Speaker, presiding.

Message from Dr. Chevalier Jackson

The Secretary read a telegram received from Dr. Chevalier Jackson, Philadelphia, who had been awarded the Distinguished Service Medal.

On motion of Dr. A. T. McCormack, Kentucky, seconded by Dr. J. E. Paullin, Section on Practice of Medicine, and carried, the House recessed at 4:10 p. m.

Third Meeting—Thursday Afternoon, June 13

The House of Delegates was called to order at 1:20 p. m. by the Speaker, Dr. H. H. Shoulders.

Report of Reference Committee on Credentials

Dr. J. Newton Hunsberger, Chairman, stated that a total of 171 delegates had been seated.

Roll Call

The Secretary called the roll and announced that more than a quorum had responded.

Presentation of the Minutes

It was moved by Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Clyde L. Cummer, Section on Dermatology and Syphilology, and carried, that the House dispense with the reading of the minutes.

Report of Reference Committee on Amendments to the Constitution and By-Laws

Dr. David D. Scannell, Chairman, presented the following report, which on motions of Dr. Scannell, duly seconded and carried, was adopted section by section and as a whole:

Two matters have been referred to the Reference Committee on Amendments to the Constitution and By-Laws:

1. Proposed Amendment to By-Laws, chapter XV, section 1: This comes from the Reference Committee on Sections and Section Work and has to do with the establishment of a Section on Anesthesiology. In the words of that reference committee, "It has been evident for several years that the physicians interested in this specialty have needed a place to discuss their scientific

papers. Your reference committee feels that the formation of such a section will fill a pressing need for the anesthetists and others who have an allied interest and recommends the establishment of such a section."

Your Reference Committee on Amendments to the Constitution and By-Laws likewise approves the establishment of a Section on Anesthesiology.

Your Reference Committee on Amendments to the Constitution and By-Laws recommends that chapter XV, section 1, of the By-Laws be amended by changing the present number "16" to number "17" and by inserting "16. Anesthesiology" after "15. Radiology," so that chapter XV, section 1, will read as follows:

SECTION 1. TITLES OF SECTIONS OF SCIENTIFIC ASSEMBLY.—The Scientific Assembly of the American Medical Association shall be divided into the following sections:

1. Practice of Medicine.
2. Surgery, General and Abdominal.
3. Obstetrics and Gynecology.
4. Ophthalmology.
5. Laryngology, Otology and Rhinology.
6. Pediatrics.
7. Pharmacology and Therapeutics.
8. Pathology and Physiology.
9. Nervous and Mental Diseases.
10. Dermatology and Syphilology.
11. Preventive and Industrial Medicine and Public Health.
12. Urology.
13. Orthopedic Surgery.
14. Gastro-Enterology and Proctology.
15. Radiology.
16. Anesthesiology.
17. Miscellaneous Topics. (As amended, 1932, 1937, 1940.)

2. (a) Report of Judicial Council Recommending Amendment to Principles of Medical Ethics, chapter III, article I, section 5: The Judicial Council feels that a study of this matter has developed certain patentable features not now included but which should be, believes that the wording of the section can be improved, and recommends that the Principles of Medical Ethics, chapter III, article I, section 5, be amended to read: "Sec. 5.—It is unprofessional to receive remuneration from patents or copyrights on surgical instruments, appliances, medicines, foods, methods or procedures. It is equally unprofessional by ownership or control of patents or copyrights either to retard or to inhibit research or to restrict the benefit to patients or to the public to be derived therefrom. It is unprofessional to accept rebates on prescriptions or appliances, or perquisites from attendants who aid in the care of patients."

Your reference committee approves the recommendation that chapter III, article 1, section 5, of the Principles of Medical Ethics be amended as suggested by the Judicial Council.

2. (b) Report of Judicial Council Dealing with Membership: This subject is discussed by the Council with the profoundest thought and honest and careful consideration. It cannot easily be summarized. Your reference committee feels that the matter is so important and vital that it should be read again, particularly for the benefit of those who did not hear it when read. This involves an amendment to the Constitution and, if adopted, would have to lie over a year for final approval.

Your reference committee approves this recommendation of a change of article 8, section 1, of the Constitution pertaining to members and Fellows and recommends its adoption.

Respectfully submitted.

DAVID D. SCANNELL, Chairman.
WILLIAM WESTON.
BARNEY D. HEIN.
CHARLES A. DUKES.
A. A. WALKER.

On motion of Dr. Scannell, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, chapter XV, section 1, of the By-Laws was amended in accordance with the recommendation contained in the report of the reference committee.

Section 5, article I, chapter III, of the Principles of Medical Ethics was amended in accordance with the report of the reference committee, on motion of Dr. Seannell, duly seconded and carried.

Resolutions Reaffirming Approval of Activities of Council on Medical Education and Hospitals

Dr. John H. Musser, Acting Chairman of the Council on Medical Education and Hospitals, presented the following resolutions:

WHEREAS, When the American Medical Association was organized in 1847 the following statement was contained in the Plan of Organization: "Inasmuch as an institution so conducted as to give frequent, united and emphatic expression to the views and aims of the Medical Profession in this country must at all times have a beneficial influence and supply more efficient means than have hitherto been available here for cultivating and advancing medical knowledge, for elevating the standard of medical education, for promoting the usefulness, honour, and interests of the Medical Profession, for enlightening and directing public opinion in regard to the duties, responsibilities and requirements of medical men, for exciting and encouraging emulation and concert of action in the profession, and for facilitating and fostering friendly intercourse between those who are engaged in it"; and

WHEREAS, In successive years the Committee on Education reported on existing conditions and made recommendations for the sound development of medical education in this country; and

WHEREAS, Immediately after the reorganization of the American Medical Association in 1902 more active measures were taken to examine and appraise the existing facilities for the training of physicians, leading, in 1904, to the establishment of the Council on Medical Education as a standing committee of the House of Delegates; and

WHEREAS, The Council conducted the first comprehensive survey of medical schools that was ever made and later secured the assistance of the Carnegie Foundation for the Advancement of Teaching, which sponsored the extraordinarily influential Flexner report; and

WHEREAS, Over a period of thirty-five years the Council on Medical Education and Hospitals has, through its inspections, reports and published classifications, steadily raised the standards of medical education and practice; and

WHEREAS, Throughout the period of its existence the Council has sought attainment of objectives equally beneficial to the medical schools, the hospitals, the interns, the medical profession and the public; therefore be it

Resolved, That the House of Delegates reaffirms its approval of the activities of the Council; and be it further

Resolved, That the Council is hereby directed to continue to discharge those functions outlined in chapter IX, section II, of the By-Laws, namely (1) to investigate conditions of medical education including pre-medical, undergraduate and graduate medical education, hospitals and associated subjects and to suggest means and methods by which the same may be improved; (2) to endeavor to further the realization of such suggestions as may be approved by the House of Delegates.

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried, the resolutions presented by Dr. Musser were adopted.

Report of Reference Committee on Miscellaneous Business

Dr. Charles G. Strickland, Chairman, presented the following report, which was adopted on motion of Dr. Strickland, seconded by Dr. A. T. McCormack, Kentucky, and carried.

On June 11 Dr. A. T. McCormack, Kentucky, introduced a resolution praising the American Museum of Health at the New York World's Fair, complimenting the city administration and suggesting the promotion of similar museums in other parts of the country.

Your reference committee recommends the adoption of that resolution.

Respectfully submitted,

CHARLES G. STRICKLAND, Chairman.
HOWARD L. SNYDER.
HENRY C. MACATEE.
FREDERIC E. SONDLIN.
HERBERT L. BRYANS.

Report of Reference Committee on Legislation and Public Relations

Dr. F. S. Crockett, Chairman, presented the following report, which was adopted section by section and as a whole, on motions of Dr. Crockett, duly seconded and carried:

REPORT OF COMMITTEE ON LEGISLATIVE ACTIVITIES

The report of the Committee on Legislative Activities reflects the current trends of legislation and social pressure on the development of medical practices. Your reference committee commends the foresight of the Committee on Legislative Activities as evidenced by the early formation of measures to insure

presentation to the Subcommittee of the Senate Committee on Education and Labor of full and adequate factual data pertinent to the Wagner bill. In the opinion of your reference committee, this activity on the part of the Committee on Legislative Activities amply justifies the wisdom of the House of Delegates in its creation. Your reference committee also commends the spirit of those physicians named in the report, who added their special skills and knowledge in testimony before the Senate subcommittee.

The federal program for the building of Veterans' hospitals beyond the apparent need of the moment has been a matter of some concern to the medical profession in the past. Much was accomplished by the Committee on Legislative Activities with the help of the American Legion in emphasizing the element of need as the determining factor in hospital construction.

Recent trends in social thinking are reflected by the proposal of the President of the United States to build hospitals with federal money in communities where the need exists. Federal measures of this type for the civilian population make more difficult our efforts to check or modify hospital construction for the care of other groups.

The Committee on Legislative Activities has followed the development of the Farm Security Administration plan for medical care of clients. This is obviously an effort to use the insurance principle to pay for medical service. It has been successful in securing cooperation of component county medical societies in many communities and, while acknowledged as experimental in scope, the experience seems to have contributed something to the solution of the medical problems of a farm group which is medically indigent.

The Committee on Legislative Activities has continued its contact with the very influential farm group, The Associated Women of the American Farm Bureau Federation. Your reference committee commends the committee for its continued effort to develop, in cooperation with this farm group, satisfactory improvements in rural medical care.

Your reference committee commends the efforts of the Committee on Legislative Activities in keeping constantly informed of legislative measures before the Congress. The profession has been unusually fortunate in having one of Dr. Cary's experience and ability to guard the ramparts of medicine's citadel against the blitzkrieg of external foes and the subversive activities of fifth columnists within our ranks.

Your reference committee, in closing, wishes to emphasize the expression of the Committee on Legislative Activities concerning the loss suffered by the profession in the death of Dr. C. B. Wright. Dr. Wright was one of those whose vision helped guide this House of Delegates in the creation of the Committee on Legislative Activities, as a member of which he served long and faithfully. The tribute of the Committee on Legislative Activities to his intelligence, mental honesty and faithfulness to his professional ideals should be reemphasized by inclusion in this report.

REPORT OF COMMITTEE TO CONFER AND CONSULT WITH PROPER FEDERAL REPRESENTATIVES

The report of Dr. Irvin Abell, Chairman of the Committee to Confer and Consult with Proper Federal Representatives, which was appointed by the House of Delegates at its special session in 1938, outlined certain principles which your reference committee wishes to reaffirm.

Since the report was prepared by Dr. Abell, a bill has been introduced in Congress and, with certain changes, passed unanimously by the Senate.

Your reference committee believes that the program for hospital construction originally suggested by President Roosevelt contained worthy objectives. This program, as contemplated in the Wagner-George bill, was reported to the Senate by the Committee on Education and Labor, which stated in part: "Your committee recognizes that the program proposed under S. 3230 is only a step toward the solution of the health problems which have received its attention for the past several months, and would provide increased hospital facilities only in localities where the need is most desperate. It is felt, however, that this measure should be immediately adopted because of the pressing necessity of the situation, and your committee has

designed the measure so it will fit into a more comprehensive program which is being formulated by your committee."

In further support of this bill, Senator Murray, chairman of the subcommittee of the Senate Committee on Education and Labor that conducted hearings on the bill, stated in part on the floor of the Senate at the time this bill was presented for consideration: "Mr. President, in conclusion I should like again to say that this proposed hospital construction program should be recognized simply as a very important step toward the solution of the national health problems which have received the committee's attention for many months. It will provide increased hospital facilities only in localities where the need is most desperate. The proposed legislation has been so designed that it can fit into a more comprehensive program which in the future may be considered desirable."

Your reference committee finds itself in harmony with the action of the House of Delegates in approving that portion of the address of President-Elect Van Etten in which he referred to the plan of the President of the United States for the construction of small hospitals with the use of federal funds in communities where actual need can be shown, provided there is strict adherence to the President's plan for construction only where actual need can be shown and then only where local governmental units can demonstrate their ability and willingness to maintain the institutions when built. Your reference committee believes that it is necessary for the medical profession to emphasize to local governmental bodies the cost of maintenance of the institutions which may be constructed under this proposed legislation.

Your reference committee appreciates the fact that this bill is in the nature of an experimental venture; it would be unfortunate if it included any provisions that might possibly militate against an adequate appraisal of its fundamental merits. It seems to your reference committee that there are several features of the bill as passed by the Senate that will create some difficulty in making that appraisal.

In the first place, the President, in his special message to Congress, contemplated only the provision of hospital beds as distinguished from medical care. The bill as passed by the Senate goes beyond this by defining a hospital to include health, diagnostic and treatment centers. Under this definition such centers may be created entirely apart from hospitals as they are generally known.

In the second place, the bill as passed requires that projects to be constructed from the appropriation made available during the first year of its operation shall be approved by the National Hospital Advisory Council. Projects to be constructed during the succeeding five year period are not subject to the approval of that council. If the approval of the council is desirable for projects to be constructed during the first year, such approval is desirable also for projects to be constructed during the succeeding five years.

In the third place, an amendment to the bill, offered by Senator Murray of Montana on the floor of the Senate, was unanimously adopted, contemplating osteopathic representation on the council. Your reference committee believes that this reference to osteopathic representation on the council is entirely unwarranted and should be eliminated from the bill.

In the fourth place, discussion has arisen with respect to the method provided in the bill for the appointment of members of the council. It has been suggested that the council should be appointed by the President.

The bill is now pending in the House Committee on Interstate and Foreign Commerce and will be given further consideration by that committee. In order that the features of the bill just discussed may be corrected, your reference committee recommends that the Bureau of Legal Medicine and Legislation be urged to continue appropriate steps to this end.

Your reference committee urges that each constituent state medical association create a special committee to act in an advisory capacity to the executive officer of the state health department on any hospital construction projects that may be contemplated under the provisions of the pending legislation.

Your reference committee believes that the House of Delegates should show its appreciation of the services of the special committee appointed by the Speaker, of the officers of the Association and of the headquarters personnel that met with the President in connection with this hospital construction pro-

gram, and recommends that this special committee be continued, to be on call by the President of the United States or other governmental authorities.

Respectfully submitted.

F. S. CROCKETT, Chairman.
CHARLES J. WHALEN.
L. G. CHRISTIAN.
WINGATE M. JOHNSON.
THOMAS A. MCGOLDRICK.

Report of Reference Committee on Executive Session

Dr. Edward R. Cuncliffe, Chairman, presented the following report, which was adopted on motion of Dr. Cuncliffe, seconded by Dr. E. G. Wood, Tennessee, and carried:

Information has come to the members of this reference committee that it is expedient to change one part of the resolution offered by the Board of Trustees and adopted by the House of Delegates last Tuesday. The ex officio members of the designated committee reside in New York and Chicago, leaving but seven members for the rest of this great country. Information from military authorities indicates that three additional members would be necessary properly to organize the United States. Therefore your reference committee recommends that that part of the resolution be changed to read as follows:

"*Resolved*, That the House of Delegates authorize the Board of Trustees to create a Committee on Medical Preparedness, to consist of ten members of this House, with the President of the Association, the Chairman of the Board of Trustees, the Secretary of the Association, the Secretary of the Board of Trustees, and the Editor as ex officio members."

EDWARD R. CUNCLIFFE, Chairman.
JAMES R. MCVAY.
J. DUFFY HANCOCK.

Report of Reference Committee on Hygiene and Public Health

Dr. E. S. Hamilton, Chairman, presented the following report, which was tabled after discussion, on motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Clyde L. Cummer, Section on Dermatology and Syphilology, and carried:

Your reference committee has reviewed the resolutions presented by the Missouri State Medical Association and wishes to report that the facts suggesting the introduction of these resolutions have not been explained and also that it has been unable to obtain the report of the special committee appointed by the Board of Trustees at the request of the House of Delegates at the 1939 session. It has waited for a communication from the Section on Ophthalmology with regard to this problem. Not having received it, your reference committee recommends that these resolutions be returned to the Board of Trustees for further information.

Your reference committee recommends that these resolutions be referred to the Board of Trustees and that the report of the committee as a whole be accepted.

Respectfully submitted.

E. S. HAMILTON, Chairman.
FELIX J. UNDERWOOD.
KARL S. J. HOHLEN.
CLYDE L. CUMMER.
W. F. DRAPER.

Resolution from the Section on Ophthalmology Requesting Appointment of a Committee on Conservation of Vision and Prevention of Blindness

Dr. Arthur J. Bedell, Section on Ophthalmology, presented the following resolution, which was adopted on motion of Dr. Bedell, seconded by Dr. Ivan Fawcett, West Virginia, and carried:

WHEREAS, One state delegation has presented resolutions to the House of Delegates; and

WHEREAS, Other state medical associations have sent their recommendations direct to the section officers; and

WHEREAS, The Section on Ophthalmology has been fully conscious of the needs for a new appraisal of the entire field of conservation of vision and prevention of blindness; and

WHEREAS, The House of Delegates is the legislative body of the American Medical Association; therefore be it

Resolved, That the Section on Ophthalmology does hereby petition the House of Delegates to approve the appointment of a Committee on Conservation of Vision and Prevention of Blindness, this committee to consist of five members of the Section on Ophthalmology who shall be responsible to the Board of Trustees; to collect data showing the status of conservation measures in each state, and to act as a clearing house for all information.

mation regarding the conservation of vision and prevention of blindness but not to make any pronouncement on policy or establish any rules until such are approved by the Section on Ophthalmology and the Board of Trustees.

Resolution from the Section on Pathology and Physiology Opposing the Formation of a Section on Experimental Medicine by Combination of Two Existing Sections

Dr. L. W. Larson, Section on Pathology and Physiology, presented the following resolution, which was adopted on motion of Dr. Larson, seconded by Dr. Wright Clarkson, Virginia, and carried:

WHEREAS, The suggestion has been made to the Council on Scientific Assembly of the American Medical Association that the Section on Pathology and Physiology be combined with the Section on Pharmacology and Therapeutics to form a Section on Experimental Medicine; be it

Resolved, That the Section on Pathology and Physiology is opposed to such a change.

Resolution from the Section on Nervous and Mental Diseases Endorsing the Formation of a Central Neuropsychiatric Institute to Be Established in the United States Public Health Service

Dr. Henry R. Viets, Section on Nervous and Mental Diseases, presented the following resolution:

WHEREAS, The Surgeon General of the United States Public Health Service in his Annual Report for 1939 stated that "Mental and nervous diseases and epilepsy together represent the largest unsolved problem in medicine. Hospitals caring for mental disease have on their books more than 500,000 patients, and more than 117,000 additional patients are cared for in hospitals for mental defectives and epileptics. These figures represent only an undetermined fraction of the total problem of mental and nervous diseases and epilepsy. Millions of dollars are spent each year for the care and treatment of such patients; but very little is expended for fundamental research which might lead to a measurable control of the problem through discoveries pointing the way to effective measures of prevention and cure." In order to remedy this condition, the Surgeon General recommended the establishment in the Public Health Service of an institute for the study of these diseases; and

WHEREAS, The Section on Nervous and Mental Diseases of the American Medical Association appreciates the magnitude of this problem and deprecates the paucity of research efforts directed toward the solution of it, and the treatment of patients in mental hospitals alone costs various governmental agencies approximately \$230,000,000 a year, and yet scarcely 1 per cent of this fund is devoted to research that might eventually lead to an appreciable reduction of the financial burden and the relief of many individuals and families of suffering and distress; therefore be it

Resolved, That the Section on Nervous and Mental Diseases of the American Medical Association go on record as endorsing a Central Neuropsychiatric Institute to be established in the Public Health Service to carry on research in nervous and mental diseases and that this institute also have at its disposal funds to be allotted to competent groups throughout the country approved by a National Neuropsychiatric Advisory Council to carry on research projects in these diseases.

Such action by this section should be transmitted to the Surgeon General of the United States Public Health Service at Washington, D. C.

It was moved by Dr. Viets and seconded by Dr. Henry A. Luce, Michigan, that this resolution be adopted. The motion was lost and the resolution was not adopted.

Resolution on Training in Legal Psychiatry, from the Section on Nervous and Mental Diseases

Dr. Henry R. Viets, Section on Nervous and Mental Diseases, presented the following resolution, which, after discussion, was tabled on motion of Dr. W. E. Kittler, Illinois, seconded by Dr. John Z. Brown, Utah, and carried:

WHEREAS, The American Medical Association has recognized the need for psychiatric participation in the disposition of criminal offenders, exemplified in its endorsement of the resolution of the American Bar Association, 1929, advocating such psychiatric participation, to wit:

Resolved: 1. That there be available to every criminal and juvenile court a psychiatric service to assist the court in the disposition of offenders.

2. That no criminal be sentenced for any felony in any case in which the judge has any discretion as to the sentence until there has been filed, as part of the record, a psychiatric report.

3. That there be a psychiatric service available to every penal and correctional institution.

4. That there be a psychiatric report on every prisoner convicted of a felony before he is released.

5. That there be established in each state a complete system of administrative transfer and parole, and that there be no decision for or against any parole or any transfer from one institution to another without a psychiatric report; and

WHEREAS, The Pennsylvania Plan sponsored by the Joint Medical-Legal Committee of the Philadelphia County Medical Society and the Philadelphia Bar Association, published as a report, March 1940, provides for the creation of an educational program combining the facilities of both an institution of learning and the state and local penal institutions

and courts, enabling qualified physicians endowed by fellowships to receive adequate training in legal psychiatry; and

WHEREAS, The Pennsylvania Plan represents the most practical step in the fulfillment of the 1929 resolution of the American Bar Association and the American Medical Association, and would create an important educational service hitherto neglected in the field of mental medicine; and

WHEREAS, The Pennsylvania Plan has received the full approval by the American Psychiatric Association, ninety-sixth annual session, Cincinnati, 1940, and by other learned bodies; therefore be it

Resolved, That the Section on Nervous and Mental Diseases of the American Medical Association go on record as endorsing the Pennsylvania Plan.

Report of Reference Committee on Reapportionment of Delegates

Dr. A. T. McCormack, Chairman, presented the following report, which was adopted on motion of Dr. McCormack, seconded by Dr. Harvey F. Garrison, Mississippi, and carried:

Reapportionment of Delegates

174			175

The total voting membership of the House of Delegates shall not exceed 175.

Your reference committee has made a careful study of the membership and recommends that the basis of the apportionment of delegates for the next three years be one delegate for each 930 members or fraction thereof, each constituent association being represented by at least one delegate irrespective of the number of members.

The By-Laws specifically provide that the total membership of the House of Delegates shall not exceed 175. The total membership of the Association on April 1, 1940, as recorded in the office of the Secretary, was 116,266.

The House of Delegates has added one section to the Scientific Assembly, which is entitled to one delegate.

On the basis of one delegate for each 930 members or fraction thereof, the total membership of the House will be 175, which is one more than the present membership of the House. On this basis California, Minnesota, New Jersey and North Carolina will each gain one delegate, while Massachusetts, Tennessee, Texas and Virginia will each lose one delegate.

Your reference committee further recommends that the Judicial Council be instructed to study the advisability of an amendment to the By-Laws that will provide that no section shall be represented by a delegate after the next reapportionment which has had an average membership registration of less than 200 over the three year period preceding reapportionment.

A. T. McCORMACK, Chairman.
H. B. EVERETT.
WILLIAM A. ELLINGWOOD.
H. H. SHOULDERS.
OLIN WEST.

Messages from National Medical Association

On request of the Speaker, the Secretary read the following telegrams, the first addressed to Dr. Nathan B. Van Eetten, President of the American Medical Association, and the second addressed to Dr. H. H. Shoulders, Speaker of the House of Delegates:

Government's request for mobilization of medical men by county societies, may I not ask you to include Negro physicians for mutual cooperation. Dr. Roscoe C. Giles, chairman, Liaison Committee, National Medical Association, named to confer with you. Shall appreciate any courtesy shown him.

A. W. DUMAS SR., M.D., President, National Medical Association, has instructed me to confer with American Medical Association with reference to inclusion in proposed program for national defense and to pledge our wholehearted support of program. Will be in Surgical Section.

ROS COE C. GILES.

The Speaker referred these telegrams to the Chairman of the Committee on Medical Preparedness that is to be appointed.

Message from Puerto Rico

At the request of Dr. Manuel de la Pila, Puerto Rico, the House instructed the Secretary to read a message signed by Dr. Pila, as follows:

As representative of Puerto Rico in the House of Delegates and voicing the spirit of the medical profession of our island, I desire to express our pride and happiness in having joined our destiny in history to that of this great democracy.

In these times when our thoughts, emotions and feelings are being so vitally affected, the medical profession of Puerto Rico wishes to make a solemn declaration. Even as Puerto Rico is today the Gibraltar of America, so does the medical profession of Puerto Rico desire to be the advance fortress in the defense of the ideals and traditions of this great country.

MANUEL DE LA PILA.

Committee on Medical Preparedness

Dr. H. H. Shoulders, Speaker, in accordance with the action of the House of Delegates on the Resolutions Authorizing Organization of a Committee on Medical Preparedness, appointed the following named ten members of the House to serve with the five ex officio members named in the resolutions: Irvin Abell, Louisville, Ky., Chairman; Stanley H. Osborn, Hartford, Conn.; Walter G. Phippen, Salem, Mass.; Harvey B. Stone, Baltimore; James E. Paullin, Atlanta, Ga.; Fred W. Rankin, Lexington, Ky.; Roy W. Fouts, Omaha; Samuel E. Thompson, Kerrville, Texas; Charles A. Dukes, Oakland, Calif.; John H. O'Shea, Spokane, Wash.

ELECTION OF OFFICERS

The Speaker declared the next order of business to be the election of officers.

Election of President-Elect

Dr. David D. Scannell, in behalf of the Massachusetts delegation, nominated for President-Elect Dr. Frank H. Lahey, Boston, and the nomination was seconded by Drs. James E. Paullin, Section on Practice of Medicine; John H. O'Shea, Washington; A. A. Walker, Alabama; E. G. Wood, Tennessee, and many others.

Dr. A. T. McCormack moved that the nominations be closed, that the rules be suspended and that the Secretary be instructed to cast the ballot of the House for Dr. Frank H. Lahey as

President-Elect. The motion was seconded by several and carried.

The Secretary cast the ballot of the House for Dr. Frank H. Lahey, Boston, for President-Elect of the American Medical Association, and the Speaker declared Dr. Lahey so elected.

Election of Vice President

Dr. Ben R. McClellan, Ohio, placed in nomination for Vice President Dr. Parke G. Smith, Cincinnati, and the nomination was seconded by Dr. Clyde L. Cummer, Section on Dermatology and Syphilology, and Dr. Barney J. Hein, Ohio.

The nominations were closed on motion of Dr. Clyde L. Cummer, Section on Dermatology and Syphilology, seconded by Dr. George Gray Ward, Section on Obstetrics and Gynecology, and Dr. Felix J. Underwood, Mississippi, and carried.

Dr. Parke G. Smith, being the only nominee for Vice President, and receiving the unanimous vote of the House for that office, was declared by the Speaker to be unanimously elected Vice President of the American Medical Association for the ensuing year.

Election of Secretary

Dr. William R. Brooksher, Arkansas, nominated Dr. Olin West, Chicago, to succeed himself as Secretary, and the nomination was seconded by Drs. Harvey F. Garrison, Mississippi; James Q. Graves, Louisiana; E. G. Wood, Tennessee; Felix J. Underwood, Mississippi; William Weston, Section on Pediatrics; R. E. Schlueter, Missouri; Charles A. Dukes, California; Peter Irving, New York; J. Newton Hunsberger, Pennsylvania, and others.

Dr. T. K. Gruber, Michigan, moved that the nominations be closed, and the motion was seconded by Dr. Felix J. Underwood, Mississippi, and carried unanimously.

After the vote of the House had been cast, the Speaker declared Dr. Olin West formally elected to succeed himself as Secretary of the American Medical Association for the ensuing year.

Election of Treasurer

Dr. Arthur W. Booth, Chairman of the Board of Trustees, stated that the Board of Trustees authorized him to put in nomination for the office of Treasurer the name of Dr. Herman L. Kretschmer, Chicago, to succeed himself.

Dr. Walter E. Vest, West Virginia, moved that the nomination be confirmed, and the motion was seconded by Dr. George W. Kosmak, New York, and carried, and the Speaker declared Dr. Herman L. Kretschmer elected as Treasurer of the American Medical Association for the ensuing year.

Election of Speaker of the House of Delegates

Dr. R. W. Fouts, Vice Speaker, took the Chair and stated that the next order of business was the election of a Speaker of the House of Delegates.

Dr. Harvey F. Garrison, Mississippi, nominated Dr. Harrison H. Shoulders, Nashville, Tenn., to succeed himself as Speaker of the House of Delegates, and the nomination was seconded by Drs. H. B. Everett, Tennessee; William H. Myers, Georgia; William Weston, Section on Pediatrics; R. E. Schlueter, Missouri; Peter Irving, New York, and James Q. Graves, Louisiana.

Dr. H. B. Everett, Tennessee, moved that the nominations be closed, and the motion was seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried unanimously.

On motion of Dr. John Z. Brown, Utah, seconded by Dr. H. B. Everett, Tennessee, and carried unanimously, Dr. Harrison H. Shoulders was elected Speaker of the House of Delegates for the ensuing year and the Vice Speaker declared him so elected.

Address of President-Elect Frank H. Lahey

The Speaker resumed the Chair, after which Dr. Arthur T. McCormack, Kentucky, presented to the House of Delegates the President-Elect, Dr. Frank H. Lahey, Boston, who addressed the House as follows:

President Van Eetten, Mr. Speaker of the House, Delegates and Friends:

I am certain that my closest friend and my most severe critic would not believe me, after my experience as a speaker, if I said that I am at a loss for words. I hesitate to inject at this time even a trace of facetiousness, but the late Dr. Coffey once

said to Mrs. Lahey that all Irishmen if awakened from a sound sleep would wake up talking. I really feel certain that anything that I say at this moment will be inadequate. I realize fully that there is but little personal element to this, and that to be promoted to the position of President-Elect of the parent medical association, representing, as it does, all of American medicine, is one of the greatest honors that can come to a man. I accept it as an instrument and not as an individual.

I see myself promoted to this position largely as an institution involved in postgraduate teaching, and I am certain that if you feel I have earned this honor it is because of this.

I realize fully the magnitude of Dr. Van Etten's undertaking, and I equally realize what the magnitude of the undertaking may be for all of us in these times, which can be characterized as little less than an emergency. I feel very strongly that if we view these times as an emergency we make only the mistake of exaggeration, for which the penalty is little, but if we view them as less than an emergency we make the mistake of minimizing them, for which the penalty may be tremendous.

I hope as we approach this very serious problem (this will not be a speech) that we can smooth out and eliminate at least in terms of a truce or a moratorium the difficulties which have beset medicine, at least until we can face and meet this emergency and overcome some of these difficulties which are so apparent at the present time. It would be wrong for me not to express my personal opinion that we can so overcome them and so harmoniously deal with the situation that other lines of endeavor will be prompted to emulate us, not the least important of which is government. Thank you very much.

Election of Vice Speaker of the House of Delegates

Dr. James Q. Graves, Louisiana, nominated Dr. R. W. Fouts, Omaha, to succeed himself as Vice Speaker of the House of Delegates and the nomination was seconded by Dr. H. B. Everett, Tennessee.

Dr. William Weston, Section on Pediatrics, moved that the nominations be closed, and the motion was seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried unanimously.

After the vote of the House had been cast, the Speaker declared Dr. R. W. Fouts formally elected to succeed himself as Vice Speaker of the House of Delegates for the ensuing year.

Election of Trustees

The Speaker declared the next order of business to be the election of two Trustees, each to serve five years, to succeed Drs. Ralph A. Fenton, Portland, Ore., and James R. Bloss, Huntington, W. Va.

Dr. John H. Fitzgibbon, Oregon, nominated Dr. Ralph A. Fenton, Portland, Ore., to succeed himself as Trustee, and the nomination was seconded by Dr. George W. Kosmak, New York; Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology; Dr. Harvey F. Garrison, Mississippi; Dr. E. H. Cary, Texas; Dr. G. Henry Mundt, Illinois; Dr. Charles A. Dukes, California, and Dr. Wells P. Eagleton, New Jersey.

Dr. John Z. Brown, Utah, moved that the nominations be closed, and the motion was seconded by Dr. James E. Paullin, Section on Practice of Medicine, and Dr. R. E. Schlueter, Missouri, and carried.

After the vote of the House had been cast, the Speaker declared Dr. Ralph A. Fenton duly elected Trustee for a term of five years to succeed himself.

Dr. Walter E. Vest, West Virginia, placed in nomination the name of Dr. James R. Bloss, Huntington, W. Va., to succeed himself as Trustee for a term of five years and the nomination was seconded by Dr. A. T. McCormack, Kentucky; Dr. George W. Kosmak, New York; Dr. Harvey F. Garrison, Mississippi; Dr. William Weston, Section on Pediatrics; Dr. George Gray Ward, Section on Obstetrics and Gynecology; Dr. H. B. Everett, Tennessee; Dr. E. G. Wood, Tennessee; Dr. Wells P. Eagleton, New Jersey; Dr. George P. Johnston, Wyoming, and Dr. Samuel P. Mengel, Pennsylvania.

On motion of Dr. Howard L. Snyder, Kansas, seconded by Dr. James E. Paullin, Section on Practice of Medicine, and carried unanimously, the nominations were closed and, after the vote of the House had been cast, the Speaker declared

Dr. James R. Bloss, Huntington, W. Va., elected to succeed himself as a Trustee for a term of five years.

The Speaker announced that there was another vacancy on the Board of Trustees, created by the death of Dr. Charles B. Wright, for a term ending in 1943, and Dr. Francis J. Savage, Minnesota, placed in nomination the name of Dr. William F. Braasch, Rochester, Minn. The nomination was seconded by Drs. Charles W. Roberts, on behalf of the Georgia delegation; Harvey F. Garrison, Mississippi; Harvey B. Stone, Maryland; James C. Sargent, on behalf of the Wisconsin delegation; H. B. Everett, Tennessee, and H. C. Bumpus, Section on Urology.

Dr. Arthur J. Bedell, Section on Ophthalmology, moved that the nominations be closed, and the motion was seconded by Dr. Harvey F. Garrison, Mississippi, and unanimously carried.

The Speaker, after the vote of the House had been cast, declared Dr. William F. Braasch elected to succeed the late Dr. Charles B. Wright for the unexpired term ending in 1943.

Nominations for Standing Committees

Dr. Nathan B. Van Etten, President, submitted the following nominations for standing committees:

Dr. George Edward Follansbee, Cleveland, to succeed himself on the Judicial Council, for a term ending in 1945.

Dr. A. A. Walker, Birmingham, Ala., to succeed himself on the Council on Scientific Assembly, for a term ending in 1945.

Dr. Arthur T. McCormack, Kentucky, moved that the nominations be confirmed and the nominees be elected to their respective positions, and the motion was seconded by Dr. Clyde L. Cummer, Section on Dermatology and Syphilology, and carried unanimously.

Dr. Arthur W. Booth, Chairman, stated that the Board of Trustees desired to place in nomination for member of the Council on Medical Education and Hospitals the name of Dr. John H. Musser, New Orleans, for a term ending in 1947. On motion of Dr. James Q. Graves, Louisiana, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried unanimously, the nomination was confirmed.

Dr. Arthur W. Booth, Chairman of the Board of Trustees, called attention to the fact that the President-Elect was a member of the Council on Medical Education and Hospitals and desired at this time the privilege of retiring, so that there would be another vacancy on that Council.

Dr. Frank H. Lahey, President-Elect submitted his resignation as a member of the Council on Medical Education and Hospitals, which was accepted on motion of Dr. Felix J. Underwood, Mississippi, seconded by Dr. Joseph F. Smith, Wisconsin, and carried. Dr. Arthur W. Booth, Chairman, then stated that the Board of Trustees desired to place in nomination Dr. Herman G. Weiskotten, Syracuse, N. Y., to fill the unexpired term of Dr. Lahey ending in 1945.

The nomination was confirmed, on motion of Dr. George W. Kosmak, New York, seconded by Dr. James E. Paullin, Section on Practice of Medicine, and carried.

Election of Affiliate and Associate Fellows

The Secretary presented the following nominations for Affiliate and Associate Fellowship, which, on motions duly seconded and carried, were confirmed by the House:

NOMINATIONS FOR AFFILIATE FELLOWSHIP APPROVED BY THE COUNCIL ON SCIENTIFIC ASSEMBLY

Beck, Lerol, St. Joseph, Mo.	Launcester, Herschel W., Nevada, Mo.
Brothhead, George L., New York.	Lanning, J. H., Kansas City, Mo.
Cheney, William E., Boston.	Lederman, M. D., New York.
Clarke, J. Frederic, Fairfield, Iowa.	MacCarthy, F. H., Laconia, N. H.
Davis, Charles E., Honolulu.	May, James V., Watertown, Mass.
Dawson, Lewis R., Seattle.	Mishoff, I. D., Milwaukee.
DeLamater, Hasbrouck, St. Joseph, Mo.	Robison, John A., Chicago.
Durkee, John W., Morristown, N. J.	Russell, James M., Monett, Mo.
Feusterer, G. A., Garden City, N. J.	Schladermundt, Charles A., Buffalo.
Fleming, Ernest William, Los Angeles.	Shreets, Vaughn L., Chicago.
Frazier, J. M., Helton, Texas.	Simpson, James Y., Houston, Texas.
Gilbert, William H., West Los Angeles, Calif.	Spitz, Louis, Philadelphia.
Hafford, George C., Albion, Mich.	Starbird, E. P., Boston.
Hays, T. A., Burns City, Ind.	Stewart, Edward S., Plainfield, Ill.
Hunston, Charles E., Chicago.	Thompson, William H., Winteret, Iowa.
Johnson, J. R., Syracuse, N. Y.	Walsh, James J., New York.
Kober, A. F., Charles City, Iowa.	Wilcox, DeWitt G., Newton Center, Mass.
Winfield, Morris, Philadelphia.	

NOMINATIONS OF AMERICAN MEDICAL MISSIONARIES FOR
ASSOCIATE FELLOWSHIP APPROVED BY THE
JUDICIAL COUNCIL

Gass, Herbert Hermann, Baitalpur, India.
Hiscox, Elizabeth J., Nuzvid, South India.
Karcher, James F., Canton, China.
Lawson, Chester W., Hong Kong, China.
Nute, William L., Talas, Turkey.
Wylie, J. Herman, Peiping, China.

NOMINATIONS FOR ASSOCIATE FELLOWSHIP APPROVED
BY THE SECTIONS INDICATED

PHARMACOLOGY AND THERAPEUTICS

Edmunds, C. W., Ann Arbor, Mich.

PATHOLOGY AND PHYSIOLOGY

Maison, George L., St. Louis.
Wiggers, Carl J., Cleveland.

NERVOUS AND MENTAL DISEASES

Overholser, Winfred, Washington, D. C.
Walker, A. Earl, Chicago.

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC
HEALTH

Corwin, Edward Henry L., New York.

Remarks by Dr. Irvin Abell

Dr. Irvin Abell, Chairman of the Committee on Medical Preparedness, addressed the House as follows:

Mr. Speaker and Members of the House:

Your action today places at the disposal of the government the entire facilities of the American Medical Association in the development of its preparedness program. The members of this Association have never been lacking in patriotism. I need but to recall to your attention that during World War No. 1 more than 30,000 of our members served with the armed forces of the United States and many thousands more served as chairmen of boards, members of boards, examiners and in various other capacities. Since the organization of the American Medical Association there has never been an emergency confronting our government in which its facilities have not wholeheartedly, unreservedly, been placed at the disposal of the government.

The duties of this committee have not been definitely defined, though I am sure that in our efforts to find out how we can best serve you, in consultation with the members of the organization itself, in consultation with the Surgeon General of the Army and the Surgeon General of the Navy, ways and means will be immediately developed, serving thus as your instrument to carry into fruition your desires and your wishes.

I happen to have in my hand an information card that was used by the Canadian Medical Association, and it is one that is easily applicable to our own membership, so that in sending such cards to each and every member of the profession in the country we can have some accurate information as to their training, their age, their qualifications and the type of work in which they are engaged. The Canadian Medical Association asked its members these questions, which I should like to read to you.

In the national emergency I am prepared to offer my services:

1. For whole-time service abroad.
2. For whole-time service in any part of the continent.
3. For whole-time service in my own locality.
4. For part-time service in my own locality.
5. I am unable to offer my services in any military capacity.

I am sure you will be interested in knowing that of 8,553 members of that association more than 90 per cent placed their services at the disposal of the Canadian government, there being but a few more than 800 who declined to take any part, for various reasons, in the program of the government.

I should like very much if the members of your committee would meet at 4:30 for a preliminary meeting, and I assure the House of Delegates that your committee will immediately go to work and as far as lies within its capacity it will endeavor to bring to the people of this country and to the government your wishes and your orders. In fact, we place our services and our facilities at the disposal of the government for its use.

Place of 1943 Annual Session

Dr. Arthur W. Booth, Chairman of the Board of Trustees, presented the following report:

The Board of Trustees wishes to report that invitations for the 1943 annual session of the Association have been received from St. Louis, San Francisco and Detroit; that St. Louis and San Francisco are qualified to accommodate an annual session of this Association, and that Detroit is less well qualified for the holding of an annual session.

Dr. R. E. Schluter, Missouri, presented an invitation from the St. Louis Medical Society, the Missouri State Medical Association and the people of the city of St. Louis to meet in St. Louis in 1943.

Dr. Elbridge J. Best, California, extended an invitation from the San Francisco County Medical Society, the California Medical Association, Mayor Rossi of the city of San Francisco, President Ray Lyman Wilbur of Stanford University and President Robert G. Sproule of the University of California to meet in San Francisco in 1943.

Dr. Burt R. Shurly, Section on Laryngology, Otology, and Rhinology, extended an invitation from the Wayne County Medical Society and the Michigan State Medical Society to meet in Detroit in 1943.

The tellers spread the ballot, on request of the Speaker, and the Secretary announced that 165 delegates had been reported present and that 142 votes had been cast, of which San Francisco received 65, St. Louis 46 and Detroit 31.

The Vice Speaker, Dr. R. W. Fouts, took the Chair and announced that, as no city had received a majority of votes, another ballot was necessary and that under the custom of the House the place receiving the lowest number should be eliminated.

The Secretary announced that the result of the second ballot was that, of 144 votes cast, San Francisco received 94 and St. Louis 50.

The Speaker resumed the Chair and declared that the House of Delegates had selected San Francisco in which to hold the 1943 annual session of the American Medical Association.

Resolution Expressing Appreciation

Dr. Arthur W. Booth, Chairman, Board of Trustees, presented the following resolution, which, on motion of Dr. Arthur T. McCormack, Kentucky, seconded by Dr. John Z. Brown, Utah, and carried, was adopted by a rising vote:

WHEREAS, The Ninety-First Annual Session of the American Medical Association held in New York in 1940 has already exceeded in total registration 11,700, the largest number by far ever in attendance at any medical convention in the world; and

WHEREAS, The facilities for housing the membership, for their entertainment, for holding scientific sessions and for the general work of the session have been exceptional in quantity and in quality; and

WHEREAS, The opportunity for dissemination of information arising from this annual session, including the general press and periodicals, has been extraordinarily comprehensive, notwithstanding even the demands on space created by the world war; and

WHEREAS, The great radio broadcasting agencies and all of the local radio stations in the city of New York have been exceedingly generous of time in broadcasting to the city, the state and the nation the news of this annual session and have utilized their facilities also for health education to the public; and

WHEREAS, The technical and scientific exhibits, even though presented under some difficulties, have attracted thousands of physicians and are larger in quantity and superior in quality to any such expositions previously held; therefore be it

Resolved, That the House of Delegates of the American Medical Association expresses its appreciation specifically to the county and state medical societies of New York, to the Chamber of Commerce, to the association of hotels, to the press, to the radio and to the citizens of New York for the magnificent cooperation and generous hospitality extended to the physicians of the country on this occasion.

Votes of Appreciation

On motion of Dr. A. A. Herold, Louisiana, seconded and carried unanimously, a rising vote of appreciation was extended to Dr. Charles Gordon Heyd, Chairman of the Local Committee on Arrangements.

A rising vote of appreciation was extended to the Speaker and the Vice Speaker of the House of Delegates.

The House of Delegates adjourned sine die at 4:05 p. m., on motion of Dr. H. B. Everett, Tennessee, duly seconded and carried.

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit at the New York session was shown for the forty-second time. There were 245 exhibits in all, 199 of which were presented under the auspices of the various sections, twenty-four in the exhibit symposium on heart disease and sixteen in the educational classification. There were three special exhibits subsidized by the Board of Trustees and three groups of motion pictures presented in conjunction with the different sections. More than 850 exhibitors, demonstrators and assistants took part in the Scientific Exhibit.

The Special Exhibit on Fractures was presented for the tenth time under the auspices of a committee composed of Dr. Kellogg Speed, Chicago, chairman; Dr. Frank D. Dickson, Kansas City, Mo., and Dr. Walter Estell Lee, Philadelphia. Dr. Henry H. Ritter, New York, served as local representative. Appreciation is expressed to Major General James Magee, Surgeon General United States Army, and Colonel F. W. Weed, Headquarters, Second Corps Area, Governors Island, New York, for assistance in furnishing personnel and material for the exhibit, and to the New York Postgraduate Hospital for furnishing two nurses—Miss Helen Behan and Miss Eileen Lombard. Fifty physicians assisted with demonstrations in six booths continuously throughout the week.

The Special Exhibit on Fresh Pathology was presented after a lapse of several years. Demonstrations took place continuously throughout the week showing fresh specimens from more than a hundred necropsies. A feature of the exhibit was the projection on a screen of interesting specimens with lectures several times a day. The committee in charge of the exhibit consisted of Dr. Harrison S. Martland, Newark, N. J., chairman; Dr. Gilbert J. Dalldorf, Valhalla, N. Y., and Dr. Milton Helpner, New York.

The Special Exhibit on Lame Backs was a new feature shown for the first time this year. A group of more than fifty physicians participated actively throughout the week in presenting the demonstrations, while a group of soldiers from the United States Army took part under the auspices of the Surgeon General. The committee in charge consisted of Dr. Frank R. Ober, Boston, chairman; Dr. Carl E. Badgley, Ann Arbor, Mich.; Dr. J. Archer O'Reilly, St. Louis; Dr. Arthur Steindler, Iowa City, and Dr. Philip D. Wilson, New York.

The Exhibit Symposium on Heart Disease and on Peripheral Vascular Disease was presented with the cooperation of

the American Heart Association under the guidance of a committee composed of Dr. Thomas M. McMillan and Dr. Norman E. Freeman, Philadelphia.

The Exhibit Symposium on Nutrition was presented as part of the exhibit from the Section on Pediatrics.

Forty papers read before the various sections of the Scientific Assembly were correlated with the exhibits in the Scientific Exhibit.

The following physicians served as representatives in the Scientific Exhibit from the different sections of the Scientific Assembly:

Section on Practice of Medicine, Dr. Fred M. Smith, Iowa City.

Section on Surgery, General and Abdominal, Dr. Grover C. Penberthy, Detroit.

Section on Obstetrics and Gynecology, Dr. H. Close Hessel-tine, Chicago.

Section on Ophthalmology, Dr. Georgiana Dvorak Theobald, Oak Park, Ill.

Section on Laryngology, Otology and Rhinology, Dr. Daniel S. Cuning, New York.

Section on Pediatrics, Dr. Arthur F. Abt, Chicago.

Section on Pharmacology and Therapeutics, Dr. Wallace M. Yater, Washington, D. C.

Section on Pathology and Physiology, Dr. F. W. Konzelmann, Philadelphia.

Section on Nervous and Mental Diseases, Dr. F. P. Moersch, Rochester, Minn.

Section on Dermatology and Syphilology, Dr. Hamilton Montgomery, Rochester, Minn.

Section on Preventive and Industrial Medicine and Public Health, Dr. Paul A. Davis, Akron, Ohio.

Section on Urology, Dr. John H. Morrissey, New York.

Section on Orthopedic Surgery, Dr. Mather Cleveland, New York.

Section on Gastro-Enterology and Proctology, Dr. Sara M. Jordan, Boston.

Section on Radiology, Dr. S. W. Donaldson, Ann Arbor, Mich.

Section on Miscellaneous Topics, Session on Anesthesia, Dr. Henry S. Ruth, Merion, Pa.

REPORT OF THE COMMITTEE ON AWARDS

The Committee on Awards made the following report:

GROUP I

(Awards in Group I are made for exhibits of individual investigation, which are judged on the basis of originality and excellence of presentation.)

The GOLD MEDAL to Charles B. Huggins, Phillip Clark and W. W. Scott, University of Chicago, Chicago, for exhibit illustrating experimental benign hypertrophy of the prostate in the dog.

The SILVER MEDAL to John R. Paul and James D. Trask, Yale University School of Medicine, New Haven, Conn., for exhibit illustrating a rural epidemic of poliomyelitis; clinical and geographic features.

The BRONZE MEDAL to Charles F. Nelson and Roland C. Nelson, the Nelson Clinic, Beverly Hills, Calif., for exhibit on bone metabolism.

CERTIFICATES OF MERIT, Group I, are awarded to the following (alphabetically arranged):

E. E. Barksdale, Danville, Va., for exhibit illustrating cutaneous manifestation from tobacco with special reference to arsenical exfoliative dermatitis.

A. E. Bennett, A. R. McIntyre and A. L. Bennett, University of Nebraska College of Medicine, Omaha, for exhibit illustrating pharmacologic and clinical investigations with crude curare.

Frederick A. Gibbs, W. G. Lennox and A. M. Grass, Boston City Hospital, Boston, for exhibit illustrating recent advances in electro-encephalography.

F. W. Hartman, Roy D. McClure, J. G. Schnedorf and Victor Schelling, Henry Ford Hospital, Detroit, for exhibit illustrating anoxia as related to anesthesia: production, prevention, treatment and pathology.

Icie Macy-Hoobler, Detroit, for exhibit illustrating chemistry of growth and nutrition in childhood.

L. S. Stone and Frederick A. Wies, Yale University School of Medicine, New Haven, for exhibit illustrating return of vision in the vertebrate eye following repeated transplantations.

In addition, the following exhibits are deemed worthy of Honorable Mention (alphabetically arranged):

That of Norman W. Elton, Millard Fillmore Hospital, Buffalo, on the defective scar of high cesarean section.

That of Reuben L. Kahn, Ann Arbor, Mich., on the detection of false positive reactions in serodiagnosis of syphilis.

That of W. J. MacNeal, Martha Jane Spence and Marie Wasseen, New York, on experimental endocarditis induced by intravenous inoculation of *Streptococcus viridans*.

That of Frank L. Meleney and Elizabeth Spofford, New York, on chronic undermining burrowing ulcers and progressive bacterial synergistic gangrene before and after treatment with zinc peroxide.

That of Louis Schwartz, National Institute of Health, Bethesda, Md., Edward A. Oliver, Chicago, and Leon H. Warren, National Institute of Health, Bethesda, Md., on occupational leukoderma.

That of William Firth Wells, University of Pennsylvania School of Medicine, and Max B. Lurie, Henry Phipps Institute, Philadelphia, on experimental air-borne disease.

GROUP II

(Awards in Group II are made for exhibits which do not exemplify purely experimental studies and which are judged on the basis of excellence of presentation and correlation of facts.)

The GOLD MEDAL to Norman Treves, Memorial Hospital, New York, for exhibit illustrating the significance of the bleeding nipple.

The SILVER MEDAL to A. H. Logan, P. W. Brown, J. A. Bargen, H. M. Weber, L. A. Buie, H. H. Bowing, A. H. Baggenstoss, C. F. Dixon, J. deJ. Pemberton and C. W. Mayo, Mayo Clinic, Rochester, Minn., for exhibit on polyps of rectum and colon and illustrating what can be done about them.

The BRONZE MEDAL to W. H. Wright, National Institute of Health, Washington, D. C., for exhibit illustrating the public health aspects of trichinosis.

CERTIFICATES OF MERIT, Group II, are awarded to the following (alphabetically arranged):

Rhoda W. Benham and Edward D. DeLamater, Columbia University, New York, for exhibit illustrating yeastlike parasites of the skin; Candida (Monilia), Cryptococcus, Pityrosporum.

F. H. Falls, University of Illinois, and Charlotte S. Holt, Illinois State Department of Public Health, Chicago, for exhibit illustrating ectopic pregnancy.

R. K. Ghormley, E. F. Rosenberg and P. S. Hench, Mayo Clinic, Rochester, Minn., for exhibit illustrating types of rheumatic diseases.

R. K. Gilchrist, Chicago, for exhibit illustrating surgical pathologic studies of carcinoma of the rectum and colon.

S. W. Harrington, Mayo Clinic, Rochester, Minn., for exhibit illustrating carcinoma of the breast.

Arnold S. Jackson, Madison, Wis., for exhibit illustrating goiter and other diseases of the thyroid gland.

In addition, the following exhibits are deemed worthy of Honorable Mention (alphabetically arranged):

That of David I. Abramson and Fanny A. Senior, May Institute for Medical Research, Jewish Hospital, Cincinnati, for exhibit illustrating plethysmographic method for the study of blood flow and vascular responses in the extremities.

That of Alfred Angrist, Jamaica, N. Y., and Richard Grimes, Forest Hills, N. Y., for exhibit demonstrating forms of intracranial hemorrhage.

That of Joseph C. Gerneroy, Henry Ford Hospital, Detroit, for exhibit on stereoscopic photographs of the eye.

That of E. S. Gurdjian, Detroit, for exhibit illustrating surgical management and surgical pathology of acute head injury; problem of fluid intake, sedatives and narcotics.

That of Robert K. Lambert, New York, for exhibit illustrating significant structural features of the ocular circulation.

That of Irvine H. Page, K. G. Kohlstadt, A. C. Corcoran, O. M. Helmer, P. J. Fouts and G. F. Kempf, Indianapolis City Hospital, Indianapolis, for exhibit illustrating nature of hypertension.

EDUCATIONAL CLASSIFICATION

A Special Certificate of Merit is awarded to the American Society of Anesthetists, New York, for its exhibit on anesthesiology—historical development.

SUBSIDIZED EXHIBITS

The Committee on Awards commends highly the special exhibits on fractures, fresh pathology and lame backs sponsored by the American Medical Association. The large and interested audience at these exhibits is an indication of the need for such exhibits, the care taken in their preparation and the excellence in the method of presentation.

RECOMMENDATIONS

It is recommended that increased facilities be provided for the projection of sound as well as silent pictures, if possible, and that consideration be given to awards for motion pictures as a separate feature.

It is recommended that the Educational Classification be discontinued so that a larger number of individual exhibitors may be accommodated. Certain of such organizations may still be included in the appropriate section under the name of the individual exhibitor.

COMMENTS

This year the Committee on Awards has had unusual difficulty in deciding on the awards because of the exceptionally large number of excellent exhibits.

The increasing excellence of the Scientific Exhibit speaks for the care in the selection of exhibit representatives. This should be continued in order to secure the proper correlation of the Scientific Exhibit with the Scientific Assembly, and in order thoroughly to canvass the field for the most excellent materials.

This year the space available has been adequate under the circumstances and it is hoped that in succeeding years this may continue. Other arrangements, such as ready access to the Scientific Exhibit with adequate entrances and exits, are important and conduce to the readiness with which the message will be delivered to the visiting physician. This is emphasized in view of the unanimity of opinion in medical circles that the Scientific Exhibit is the most valuable feature of the entire annual session.

The attention of the Trustees is called to the fact that, in the Scientific Exhibit, the opportunity is provided for discovering exhibits which will be suitable for traveling exhibits for the state societies.

The Committee is also impressed with the cooperation of the Committee on Scientific Exhibit of the Board of Trustees and the Advisory Committee. The unflinching help of Dr. Thomas G. Hull, Director of the Scientific Exhibit, has been an inspiration to the undersigned.

FRED D. WEIDMAN, Philadelphia, Chairman.

HOWARD M. CLUTE, Boston.

WILLIAM S. McCANN, Rochester, N. Y.

I. C. RIGGIN, Richmond, Va.

WALTER M. SIMPSON, Dayton, Ohio.

REGISTRATION AT NEW YORK

The total registration at the New York session was 12,864. Below are summaries of the registration by sections and by states:

Registration by Sections

Practice of Medicine.....	4,338
Surgery, General and Abdominal.....	1,754
Obstetrics and Gynecology.....	864
Ophthalmology.....	601
Laryngology, Otology and Rhinology.....	509
Pediatrics.....	737
Pharmacology and Therapeutics.....	67

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

COLORADO

Midsummer Radiologic Conference.—The Denver Radiological Club will hold its annual midsummer radiologic conference at the Hotel Shirley Savoy, Denver, August 8-10.

Society News.—Dr. Herbert A. Black, Pueblo, discussed carcinoma of the cervix before the Otero County Medical Society at a recent meeting in La Junta.—Dr. Franklin G. Ebaugh, Denver, discussed insanity before the Fremont County Medical Society in Florence recently.—At a meeting of the Pueblo County Medical Society, Pueblo, May 21, Dr. Wilbur Lowe spoke on "Rectal Prolapse—Procidentia and Merits of Injection Treatment."

ILLINOIS

Personal.—Dr. Felix W. Sokolowski has resigned as managing officer of the Alton State Hospital, effective May 1, it is reported. He will devote all his time to private practice. Dr. Edward Ross, Chicago, became acting managing officer.

Course for Medical Officers.—A two months' postgraduate course in cardiovascular disease for medical officers of the Veterans Administration was recently given at Hines. Participating were:

Dr. Louis N. Katz, April 4, Clinical Value of the Electrocardiogram.
Dr. Emmett B. Bay, April 18, Hydraulics of the Circulation.
Dr. James G. Carr, April 25, Arteriosclerotic Heart Disease.
Dr. Andrew C. Ivy, May 2, Physiological Aspects of Hypertension.
Dr. Geza de Takats, May 16, Peripheral Vascular Disease.

Chicago

Course on Electrocardiography.—The cardiovascular department of Michael Reese Hospital announces a full time course in electrocardiography, August 19-31, under the direction of Dr. Louis N. Katz.

New Officers of Chicago Medical Society.—Dr. James P. Simonds has been named president-elect of the Chicago Medical Society and Dr. Frank F. Maple installed as president of the society. The ninetieth annual meeting and dinner of the society, June 25, was addressed by the outgoing president, Dr. Nathan S. Davis III, and by Dr. William Allen Pusey on "The First Ninety Years of the Society."

Dr. Kyes Made Professor Emeritus.—Dr. Preston Kyes, since 1918 professor of preventive medicine, School of Medicine of the University of Chicago, will become professor emeritus July 1. Dr. Kyes was born at North Jay, Maine, in 1875. He graduated at Johns Hopkins University School of Medicine, Baltimore, in 1900. He was a fellow of the Rockefeller Institute for Medical Research, New York, from 1902 to 1905; associate in the Chicago Memorial Institute for Infectious Diseases, 1904-1909, and Royal Prussian Institute of Experimental Therapy at Frankfurt-on-the-Main, Germany, 1901-1905. He has been associated with the University of Chicago since 1902.

Courses in Obstetrics and Pediatrics.—A series of one week courses in obstetrics and pediatrics will begin, July 8, at the University of Illinois College of Medicine, Chicago. Lecturers will include:

Dr. Frederick H. Falls, professor of obstetrics and gynecology, University of Illinois College of Medicine.
Dr. Edwin M. Miller, clinical professor of surgery, Rush Medical College.
Dr. Albert H. Montgomery, chief surgeon, Children's Memorial Hospital.
Dr. Joseph L. Baer, clinical professor of obstetrics and gynecology at Rush.
Dr. Francis E. Seneat, professor of dermatology at Illinois.
Dr. Clark W. Finnerud, assistant professor of dermatology at Rush.
Dr. William J. Dieckmann, associate professor of obstetrics and gynecology, School of Medicine, University of Chicago.
Dr. Tell Nelson, associate in medicine at Illinois.
Dr. Ben Z. Rappaport, associate in medicine at Illinois.

Information may be obtained from Mr. G. R. Moon, registrar, University of Illinois College of Medicine, 1853 West Polk Street.

MARYLAND

Portrait of Dr. Hunner.—Dr. Guy L. Hunner, since 1932 adjunct professor of gynecology, Johns Hopkins University School of Medicine, Baltimore, was honored recently when a group of workers from the department of gynecology presented a portrait of him to the university. It was the work of his daughter, Mrs. John Parsons. Dr. Hunner graduated at Johns Hopkins in 1897 and has been on its faculty since 1902.

Annual Health Conference.—The twentieth annual health conference of the field and departmental staffs of the state department of health was held in Baltimore, May 3. Speakers included:

Drs. Perrin H. Long and Horace L. Hodes, Baltimore, Use of Sulfapyridine in Treatment of Disease.
Dr. Lloyd D. Felton, Washington, D. C., Studies on Immunization Against Pneumonia.
Ira V. Hiscock, Sc.D., New Haven, Conn., Public Health Education and Its Place in a Community Health Program.
Dr. Charles H. Peckham Jr., Baltimore, Preliminary Report Based on a Study of 1,500 Births on the Obstetrical Care Available to Rural Mothers in Maryland.
Arthur W. Hedrich, Sc.D., Baltimore, Results of a Statewide Test of Birth Registration in Maryland.
Dr. Austin V. Deibert, Baltimore, The State Venereal Disease Program for 1939.

MASSACHUSETTS

State Child Guidance Clinics.—Two new child guidance clinics have been established through the efforts of the Massachusetts Society for Mental Hygiene and the cooperation of the division of mental hygiene of the state department of mental health. One is in Hamilton and the other in Marblehead. Because of the special interest of the schools in these towns, the clinics are housed in the Jonathan Lamson School in Hamilton and in the Junior High School in Marblehead, according to the *Monthly Bulletin* of the state society for mental hygiene.

Director for Infantile Paralysis Clinic.—Dr. William T. Green, assistant professor of orthopedic surgery, Harvard Medical School, Boston, has been made director of the after-care clinic of the Harvard Infantile Paralysis Commission, effective June 1. Dr. Green will have charge of one of the two main divisions of the scientific work of the commission. Located in the Children's Hospital, the clinic cares for about 1,400 children annually and conducts investigations of methods of treatment of infantile paralysis and of its after-effects. Dr. William Lloyd Aycock, assistant professor of preventive medicine and hygiene, Harvard Medical School, is in charge of the commission's division of laboratory research, including study of the causation and epidemiology of the disease. The commission was established by the Harvard Corporation in 1916. It is supported entirely by public subscription and receives no financial aid from the university. Besides supporting laboratory and clinical research, the commission also acts in an advisory capacity to the Massachusetts Department of Health and cooperates with the Vermont Board of Health.

MICHIGAN

New Building for State Health Department.—The Michigan State Department of Health plans to begin, July 1, the construction of a new four story building in northwest Lansing in conjunction with its central laboratories. WPA funds totaling \$64,999 and a state appropriation of \$50,000 will be used toward financing the building.

MINNESOTA

Personal.—Dr. Charles E. Rea has resigned as assistant professor of surgery at the University of Minnesota Medical School, Minneapolis, to enter private practice in St. Paul.—Dr. Russell R. Heim, Minneapolis, has been appointed health commissioner of Hennepin County, succeeding the late Dr. Thomas T. Warham.—Dr. Frederick W. Hoffbauer, Minneapolis, has been appointed physician on the staff of the health service of the University of Minnesota, effective September 16.—Dr. Charles L. Scofield, Benson, recently observed two anniversaries, one his seventy-fifth birthday and the other his completion of fifty years in the practice of medicine. He has been a member of the state board of health for twelve years, serving four years as president.

MISSISSIPPI

Health Department Activities.—A health department has been established in Marion County with Dr. Ralph Sneed, University, as director. Dr. Alton R. Perry, Laurel, has resigned as director of the unit in Jones County; he has held the office since the department's establishment in 1937. Dr. Ransom J. Jones, Poplarville, has been appointed director of the Leflore County Health Department; he has been in charge of

the southeastern health district, composed of George, Greene, Stone and Perry counties. He will be succeeded in the latter position by Dr. Edwin H. West, Purvis. Dr. Byron O. Garner, Greenwood, acting officer in Leflore County, has been made full time director in Noxubee County. Dr. James H. White, Corinth, acting health officer in Alcorn County, has been placed on a full time basis. Dr. Lynn D. Abernethy, Grenada, has been made director of health in Marshall County, relieving Dr. John W. Dugger, who had been acting health officer since the resignation of Dr. John W. Dorman, Dyess, Ark. Dr. Murphy M. Sims, Lexington, acting director of Holmes County, has been appointed health officer of Lafayette County, succeeding Dr. James H. Armstrong, Oxford, who resigned to enter private practice.

NEVADA

Plague Infection.—According to *Public Health Reports*, plague infection was proved in tissue from two ground squirrels, *Citellus beldingi oregonus*, found dead, April 18, on ranches 6 and 10 miles, respectively, northeast of Lamoille; in a pool of twenty fleas from six ground squirrels of the same species, shot on the same date, on a ranch 8 miles northeast of Lamoille, and in tissue from one ground squirrel, *Citellus richardsoni nevadensis*, also shot, April 18, on a ranch 5 miles west of Wells. All localities mentioned are in Elko County.

NEW YORK

Appointments to Health Council.—Dr. L. Whittington Gorham, Albany, has been appointed a member of the New York State Public Health Council to fill the vacancy created by the death of Dr. Livingston Farrand. The term will expire Dec. 31, 1942. Dr. Walter A. Leonard, Cambridge, was reappointed for a six year term.

Personal.—Dr. Arthur J. Bedell, Albany, received the honorary degree of doctor of laws at the annual commencement of St. Bonaventure's college, Alleghany, June 4.—Benjamin H. Willier, Ph.D., head of the division of biological sciences, University of Rochester, since 1933, has been appointed Henry Walters professor of zoology at Johns Hopkins University, Baltimore.

Infirmiry Named for School Physician.—A new infirmiry at Vassar College, Poughkeepsie, was named Baldwin House in honor of Dr. Jane North Baldwin, chairman of the department of health and hygiene, during dedicatory ceremonies, May 25. A tablet on the facade was unveiled by Dr. William Darrach, dean emeritus and professor of clinical surgery, at the Columbia University College of Physicians and Surgeons. Dr. Baldwin graduated at Cornell University Medical School in 1900. In 1905 she joined the medical staff at Vassar College, becoming its head in 1929. The new infirmiry has a capacity of thirty-five beds.

New York City

Military Clinical Conference.—The Metropolitan New York chapter and the New Jersey chapter of the Association of Military Surgeons of the United States held a clinical conference for medicomilitary officer personnel at the United States Marine Hospital, Stapleton, June 22. Clinical presentations were made on coronary diseases, diseases of the genito-urinary tract and gastric ulcers. Dr. Charles W. Naulty Jr., Perth Amboy, N. J., was in charge of arrangements.

Annual Graduate Fortnight.—The New York Academy of Medicine will present its annual graduate fortnight October 14-25. The theme of the meeting will be infections, with panel discussions, afternoon clinics, clinical demonstrations, evening addresses and appropriate exhibits making up the program. The purpose of the fortnight is to make a complete study and authoritative presentation of a subject of importance in the practice of medicine and surgery. A complete program and registration blank may be obtained from Dr. Mahlon Ashford, New York Academy of Medicine, 2 East One Hundred and Third Street.

Society News.—Speakers at a meeting of the New York Roentgen Society, May 20, included Drs. Lucien M. Pascucci on "Roentgen Therapy in Leukemia; Survival Period and Reaction of Spleen and Nodes" and Jacob R. Freid, "Pulmonary and Skeletal Metastases from Cancer of the Kidney, Prostate and Bladder."—Dr. William A. Antopol, Newark, N. J., among others, addressed the New York Pathological Society, May 23, on "Experimental Aspects of Heparin-Sulfapyridine in Massive Urolithiasis."—Dr. Grant P. Pennoyer addressed the New York Surgical Society, May 8, on "Peripheral Arterial Disease."—Dr. Albert D. Kaiser, Rochester, N. Y., addressed the Bronx County Medical Society,

May 15, on "Role of the Tonsils in Health and Disease."—Dr. Geza Weitzner, among others, addressed the Bronx Gynecological and Obstetrical Society, May 27, on "Treatment of Gonorrheal Salpingitis with Estrogenic Hormones."

Report of County Library.—The directing librarian of the Library of the Medical Society of the County of Kings and the Academy of Medicine of Brooklyn in his annual report stated that the library has filled all its available space. During the year it was necessary to shorten the time when the library was open to nonmembers. This resulted in a decrease of readers using the library from 17,055 in 1938 to 14,708 in 1939, yet the number of books consulted increased by 669 and the number taken out for home use decreased 2,239. This library, fourth in size of the medical libraries of the country outside of the Surgeon General's library, receives financial assistance from numerous medical societies, some dental societies and several other organizations, as well as many individuals who donate books, journals and funds. During 1939 the library added 835 volumes. It also purchased 807 volumes of periodical publications or back files. The total number of current periodicals and serial publications now on file is 1,566, the report said. Conditions abroad have affected the receipt of current journals. Periodicals formerly received from Spain had not resumed coming to the library at the time of the report; no Polish journals had arrived since August 1939. Some French and German journals were being received irregularly.

NORTH CAROLINA

Research Fellowship in Zoology.—Establishment of the Charles W. Hargitt Research Fellowship in zoology at Duke University, Durham, is announced. The fellowship was made possible by a bequest in the will of the late Charles Wesley Hargitt, Ph.D., for many years research professor of zoology at Syracuse University, Syracuse, N. Y., who died in 1927. It is expected that the fellowship will be granted in 1941 for research in cytology. Dr. Hargitt's son, George T. Hargitt, Ph.D., is professor of zoology at Duke.

Society News.—At a meeting of the Thermal Belt Medical Society in Marion recently the speakers were Drs. Isaac A. Phifer Jr., Spartanburg, S. C., on "The Gonorrheal Problem"; Paul T. McBee, Marion, "Middle Meningeal Hemorrhage"; John C. Hamrick, Shelby, "Sutures and Suture Materials" and John W. Austin Woody, Tryon, "Maternal Health Program in Polk County."—Drs. Charles F. Glenn and Ben E. Washburn, Rutherfordton, recently addressed the Rutherford County Medical Society on "Chronic Cystic Mastitis" and "Public Health Activities in the Caribbean Region," respectively.

OHIO

Grants at Western Reserve.—The John and Mary R. Markle Foundation of New York has appropriated \$4,100 for the continuation of studies of the "Cause and Treatment of Ventricular Fibrillation" at Western Reserve University School of Medicine, Cleveland. Studies have been in progress for a year at the school and the results justify a further pursuit of the work. The Commonwealth Fund of New York has given \$17,900 to the school for a three year program of studies of extracardiac factors of circulation, the part which the blood vessels play in the blood flow, particularly in failure of the circulation in surgical shock and similar conditions. Both studies are under the direction of Dr. Carl J. Wiggers, professor of physiology at the school. The Markle Foundation has made a grant of \$2,000 to the school to support an investigation of intravenous bismuth injections by Drs. Torald H. Sollmann, professor of pharmacology and materia medica, dean and executive officer, and Joseph Seifter, senior instructor in pharmacology.

PENNSYLVANIA

Society News.—Dr. Holbert J. Nixon, Uniontown, discussed toxemias of late pregnancy before the Fayette County Medical Society in Uniontown, June 6.—Dr. Leo D. O'Donnell, Pittsburgh, discussed "Diagnosis and Treatment of Gallbladder Disease" before the McKean County Medical Society in Bradford, May 21.—Dr. Ralph M. Tyson, Philadelphia, addressed the Blair County Medical Society in Altoona, May 28, on "Blood Disorders in Infancy and Childhood."

Philadelphia

University News.—The Van Lennep Surgical Society of the Hahnemann Medical College of Philadelphia presented Dr. William F. Rienhoff Jr., Baltimore, in a lecture for students and physicians recently at the college. Dr. Rienhoff's subject was "The Present Status of the Surgical Treatment of Carcinoma of the Lung."

Annual Health Award.—The second annual award of the Pennsylvania Public Health Association this year went to Dr. Henry Field Smyth, assistant professor of industrial hygiene, University of Pennsylvania School of Medicine, and Arthur M. Dewees, executive secretary of the Pennsylvania Tuberculosis Association since 1919, for achievements in public health. At the fifteenth annual meeting of the association, May 24, when the award was presented, Harry B. Meller, Pittsburgh, was chosen president-elect and Dr. Paul A. Keeney, Harrisburg, was installed as president.

Society News.—A symposium on tuberculosis was presented before the Philadelphia Pediatric Society, May 14, by Drs. Miriam E. Brailey, Baltimore; Esmond R. Long, Philadelphia; Richard H. Smith, U. S. Public Health Service, and Josephine Shesner, R.N., U. S. Indian Service. At a meeting of the Philadelphia Neurological Society, May 24, the speakers were Drs. Ernest A. Spiegel on "Rhythmic Stimulation of the Labyrinth"; Hymen Edward Yasskin, Camden, N. J., "Rickettsial Meningo-Encephalomyelitis," and Howard A. Howe, Baltimore, "Experimental Studies on Poliomyelitis." The Philadelphia and New York urological societies held a joint meeting at Jefferson Medical College of Philadelphia recently. The speakers included Drs. Virgil H. Moon, on "Early Recognition of Shock and Its Differentiation from Hemorrhage"; Paul R. Leberman, "Studies on the Pathology of the Human Renal Papilla"; Patrick Boland Hughes, "Renal Aspects of Hypertension"; Alexander Randall, "Proof of Origin of Growth of Three Different Chemical Types of Renal Calculi," and Arthur M. Walker, "Further Experiments on Localization of Function Within the Renal Tubule."

SOUTH CAROLINA

Society News.—Dr. James E. Paullin, Atlanta, Ga., addressed the Columbia Medical Society, May 13, on "Congestive Heart Failure."—Drs. Eugene M. Landis, Richmond, Va., and Staige D. Blackford, Charlottesville, Va., addressed the Greenville County Medical Society, Greenville, May 13, on "Pathogenesis and Treatment of Edema" and "Spontaneous Pneumothorax" respectively.

Course in Obstetrics and Pediatrics.—The Medical College of the State of South Carolina has arranged for a program of instruction in obstetrics and pediatrics for South Carolina physicians. Four physicians will be taken at a time for two weeks of ward rounds and clinics with the college staff. Arrangements are made through the maternal and child health division of the state board of health.

Appointments to State Medical Board.—New appointments to the state board of medical examiners include the following: Dr. George C. Brown Jr., Walterboro, to succeed Dr. Daniel L. Maguire, resigned; Dr. Wilbur R. Tuten, Fairfax, succeeding the late Dr. Josiah S. Matthews, Denmark; Drs. Enoch M. Dibble, Marion, and Albert Earle Boozer, Columbia, were reappointed, newspapers reported.

TENNESSEE

Medical Section in Chattanooga Library.—A room to be known as the "Medical Section of the Chattanooga Public Library" is being arranged through a gift of funds and books by the Chattanooga and Hamilton County Medical Society. A collection of approximately 1,000 books and bound magazines and a large file of unbound magazines have been given to the library by the society as a nucleus of a medical library. Equipment and furniture are being provided by the library.

TEXAS

Personal.—Dr. James E. Peavy Jr., Austin, recently became director of the health unit for San Augustine and Sabine counties. Dr. Samuel D. Whitten, Greenville, has been appointed health officer of Hunt County to succeed Dr. Lemuel E. Gee, resigned. Dr. John W. Spies, dean and professor of public health, University of Texas School of Medicine, Galveston, was recently elected to the Royal Society of Tropical Medicine and Hygiene in London, according to the *Texas State Journal of Medicine*. A group of women in San Benito recently honored Dr. Clarence M. Cash by dedicating a room in the Valley Baptist Hospital, Harlingen, in his name, in recognition of his professional services in the last forty years. Dr. Cash received a portfolio of pictures of children whose birth he had attended.

Annual Interns' Night.—The Tarrant County Medical Society instituted an annual interns' night at its regular meeting in Fort Worth, May 22. The program consisted of papers

entered in the annual case report contest conducted among residents and interns of the five Fort Worth general hospitals. The first prize of \$15 was awarded to Dr. Richard G. Scobee, a recent graduate of the University of Texas School of Medicine, Galveston, an intern at Harris Memorial Methodist Hospital. His paper was entitled "Ectopic Pregnancy." The second prize of \$10 went to Dr. William D. Sedgwick, a graduate of the University of Tennessee College of Medicine, Memphis, and an intern at City-County Hospital, Fort Worth, for a paper on "Hyperglycemia and Glycosuria in Coronary Thrombosis." Honorable mention was given to Dr. James E. McConnell, a graduate of Louisiana State University School of Medicine and an intern at Harris Memorial Methodist Hospital, for a paper entitled "Acute Streptococcus Viridans Endocarditis." The winning papers will be published in the *Tarrant Medical Bulletin*.

VERMONT

Postgraduate Course for Ophthalmologists.—The College of Medicine of the University of Vermont, Burlington, held a postgraduate course for ophthalmologists in neuromuscular anomalies of the eye during the week of June 17. The sessions were held in the medical college building. The course was under the direction of the department of ophthalmology and otolaryngology, and the instructor was Dr. George P. Guibor, associate attending ophthalmologist at the Children's Memorial Hospital, Chicago.

WASHINGTON

Poliomyelitis in Tacoma.—An outbreak of poliomyelitis in Tacoma and Pierce County was reported in *Northwest Medicine* for June. Fifteen cases with four deaths had occurred up to May 21. Dr. Edward C. Rosenow, Rochester, Minn., addressed the Pierce County Medical Society, May 27, on poliomyelitis.

University of Washington Graduate Course.—The twenty-fourth annual graduate medical course at the University of Washington, Seattle, will be held July 15-19. The faculty will be:

Dr. Soma Weiss, Hersey professor of theory and practice of physics, Harvard Medical School, Boston, for medical topics.

Dr. Charles F. McKhann, associate professor of pediatrics and communicable diseases, Harvard Medical School, Boston, pediatrics.

Dr. Richard B. Cattell, the Lahey Clinic, Boston, surgery.

Chauncey Leake, Ph.D., professor of pharmacology, University of California, San Francisco, pharmacology.

Tickets may be purchased by mail from the Extension Division, Lewis Hall, University of Washington. The fee is \$10.

PUERTO RICO

University News.—Dr. Ramon M. Suarez, associate professor of tropical medicine in the School of Tropical Medicine at the University of Puerto Rico under the auspices of Columbia University, San Juan, has been made head of the department of clinical medicine. Dr. Albert V. Hardy, assistant professor of epidemiology, De Lamar Institute of Public Health, Columbia University, New York, was in Puerto Rico recently arranging for the establishment of a school of public health in the School of Tropical Medicine. It is expected that the school will open in September.

GENERAL

W. W. Buffum Dies.—Mr. William W. Buffum, treasurer and general manager of the Chemical Foundation, New York, since 1921, died at his home in Montclair, N. J., June 22, after a brief illness. He was 51 years old and a native of Pennsylvania. In 1917 Mr. Buffum joined the staff of the Alien Property Custodian in Washington, D. C., of which the late Mr. Francis P. Garvan, later president of the Chemical Foundation, was the head. Through his position with the foundation Mr. Buffum was business manager of the *American Journal of Cancer*, the *Journal of Clinical Investigation* and the *Sewage Works Journal*. At one time he was treasurer of the American Institute of Physics.

Examination in Obstetrics and Gynecology.—The next written examination and review of case histories (part I) for group B candidates of the American Board of Obstetrics and Gynecology will be held in various cities of the United States and Canada, Jan. 4, 1941. Candidates who successfully complete these examinations proceed automatically to the part II examinations held later in the year. Applications for admission to group B, part I, examinations must be on file in the secretary's office not later than October 5. The general oral and pathologic examinations (part II) for all candidates (groups A and B) will be conducted by the entire board, meeting at Cleveland immediately prior to the 1941 session of the American

Medical Association. After Jan. 1, 1942, there will be only one classification of candidates and all will be required to take part I and part II examinations. Further information and application blanks may be obtained from Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh (6), Pa.

Changes in Status of Licensure.—The California State Board of Medical Examiners has announced the following changes, among others:

Dr. Harry W. Boyd, now of Pittsburgh, license restored, February 26.
Dr. Charles W. Farley, Los Angeles, license revoked, February 29, for an alleged illegal operation.

Dr. Wendell O. Gregg, Los Angeles, placed on probation for five years, with a proviso that he does not practice from Feb. 27, 1940, until Jan. 1, 1941; that during the probation he abstain entirely from alcoholic beverages and that he shall not have in his possession a narcotic permit.

Dr. Yasuzo Karaki, Los Angeles, license revoked, February 29, for his conviction of a crime involving moral turpitude.

Dr. Eugene Curry Nelson, Los Angeles, license revoked, February 29, for an alleged illegal operation.

Dr. John Marshall Robinson Jr., Los Angeles, license revoked, February 29, for an alleged illegal operation.

Dr. Frederic Waitzfelder, Los Angeles, placed on probation for five years, February 27, without narcotic privileges.

Dr. James C. Weld, Los Angeles, license restored, February 26.

LATIN AMERICA

Personal.—Dr. José Arce, dean of the medical school of the University of Buenos Aires, recently spent a month visiting hospitals and medical schools in the United States.

Program to Control Whooping Cough.—At the request of Dr. José Zozaya, head of the National Serum Institute of Mexico, arrangements have been completed to organize a pertussis control program in the republic of Mexico under the direction of Pearl L. Kendrick, Sc.D., associate director of the Michigan Department of Health Laboratories. Dr. Kendrick, who directed the series of Michigan studies from 1934 to 1938, will assist the Mexican government for about six weeks this summer. The National Serum Institute of Mexico plans to provide a vaccine similar to that being used in Michigan and Dr. Kendrick will direct a study for checking its effectiveness in controlling the virulent type of whooping cough prevalent in Mexico, it was reported. The disease accounted for 2,000 deaths in the republic of Mexico last year and is said to be prevalent the year around.

Government Services

Chief Medical Officer Wanted

The U. S. Civil Service Commission has announced an open competitive examination to fill the position of chief of the medical division of the commission. It is urgent that the position be filled immediately. Applications will be received for only two weeks, the announcement said. Applications must be filed with the Washington office not later than July 8 if received from states east of Colorado and not later than July 11 if received from Colorado and states westward. The salary is \$6,500 a year, less a retirement deduction of 3.5 per cent. Applicants must have been graduated with an M.D. degree from a medical school of recognized standing or must be licentiates of the National Board of Medical Examiners. In addition, they must have had highly responsible professional experience in the field of medicine, partly in a managerial or supervisory capacity. Applicants obtaining the highest ratings may be requested to appear for an oral examination. Should vacancies requiring similar qualifications occur in other government agencies, they may be filled from this examination. The duties of the chief of the medical division of the Civil Service Commission will be to direct a medical program more extensive than anything the commission has yet undertaken. He will be responsible for all steps taken by the commission to control physical standards and regulations for government employees and candidates for such employment. He will act as medical adviser to the commission, interpreting medical problems in programs concerning recruiting, employment and retirement, will cooperate with other government agencies in developing employment programs and policies and will keep in touch with medical schools, hospitals and professional associations in order to maintain the best recruiting standards and also to develop types of training calculated to serve better the needs of the government. Information and application forms may be obtained from the Secretary, Board of U. S. Civil Service Examiners, at any first or second class postoffice or from the Civil Service Commission, Washington, D. C.

Foreign Letters

PARIS

(From Our Regular Correspondent)

June 2, 1940.

Alcoholic Content of Wine

A committee recently authorized by the Academy of Medicine to study the danger of excessive use of wine reported that alcohol contained in wine was as injurious as distilled alcohol. Public opinion in France, however, sides with wine against alcohol and thinks that little toxicity inheres in wine because of its diluted state and that wine can be counted among wholesome beverages. Likewise powerful organizations, such as wine growers and distillers, have a great interest at stake. The report of the chairman of the committee, Lapique, unanimously accepted by the academy, once more brings home not only to the public but to the different control agencies and the legislatures the fact that a liter of ordinary wine contains the equivalent of a glass of alcohol and that alcohol is injurious when daily consumption exceeds 100 cc. Strict regulation of alcoholic beverages was called for in the report, as well as the suppression of misleading advertising. Fournau, supporting Lapique's conclusions, pointed out that only one tenth of the alcohol imbibed was excreted by the lungs and kidneys. The remainder was oxidized in the body or rather dispersed to be oxidized and finally accumulated in the brain and the spinal fluid. When alcohol is taken in fractionated doses, a man weighing 70 Kg. (154 pounds) could oxidize 120 Gm. in twelve hours like other food. The rest remained stagnant in the tissues.

Radiopaque Injections in Bone Marrow

Raymond Benda recently presented to the Société médicale des hôpitaux of Paris the results achieved by injecting a radiopaque substance into the bone marrow of the sternum to study its vascular connections. He employed colloidal thorium dioxide. In the cadaver the roentgenogram regularly shows an area of opaque madreporic substance resembling coral reef, with the injection forming the center. Beyond, the opaque substances spread out in stellate lines with more or less curvature. The internal mammary veins are almost always invaded by the radiopaque fluid. Josefson in 1934 had tried a solution of iodine in poppyseed oil in vivo but had been unable afterward to find a trace of the injected material. Benda tried the same injection on two incurable patients, one with dementia paralytica, the other with inoperable carcinoma. The one was injected at the manubrium, the other at the sternal lamina situated at the third intercostal space. Unlike the x-ray observations in the cadaver, neither the intermediate areas nor the stellate lines were discoverable in man. The substance had spread about like small scattered grains, almost entirely within the interior of the sternum. It seems that the substance "had somehow been seized on its arrival in the bone marrow by cells in full activity." The complete harmlessness of the injections and the interest thus aroused justify further investigations.

Antitetanus Anatoxin

In about 40 per cent of adults treated with antitetanus serum, reactions are observed with one death in 50,000 vaccinations, in spite of the use of Besredka's method. Gaston Ramon on the one hand and Jeanneney, Saraste and Fauvert on the other presented the results obtained with tetanus anatoxin before a recent session of the Académie de chirurgie. In horses the anatoxin produces tetanus antitoxins. By means of the stimulating properties of certain substances such as tapioca, serums can be obtained within a few weeks whose titer attains to 4,000, 6,000 and 12,000 units, these serums containing from ten to

twenty times fewer proteins than is found in crude horse serum. Tetanus antitoxins retain their strength longer in this form than does raw horse serum. They possess one tenth of a unit strength after two weeks and do not disappear entirely at the end of a month. Denaturation by the combined action of formaldehyde and heat seems to confer on them qualities less foreign to the organism than raw horse serum. Anatoxin solutions in equivalent antitoxic values are less sensitizing than antitetanus horse serum. Reinoculated persons have fewer reactions, even those who have previously received an injection of raw horse serum. Jeanneney presented 153 cases in which anatoxin was employed prophylactically in recently wounded soldiers, fifty-two of whom (persons affected with asthma, urticaria or hepatic insufficiency) had been chosen because they were predisposed to anaphylactic reactions. In only 3 1/4 per cent of these, slight accidents manifested themselves about the fifth day, whereas in a control group twenty cases of significant serum reactions were observed. The wounded can be given prophylactic injections simultaneously with antigangrene serum and in the vaccination of young recruits it can be combined with antidiphtheria anatoxin and antityphus vaccines.

BUENOS AIRES

May 17, 1940.

Cardiac Examination of School Children

In Buenos Aires 10,000 school children have recently been subjected to a circulatory examination. First, a general examination was made in the schools; children who had cardiac murmurs or other symptoms were then subjected to a careful clinical examination. It was found that 2.4 per cent of the children had organic heart lesions. It was hoped that by the early recognition of these circulatory disturbances better results would be obtainable when the children became adults. This represents an important social problem; the investigation was carried out in the Hospital Pirovano by Dr. A. Ruecheff and R. Gay together with the medical inspector, J. M. Macera.

The cardio-articular rheumatism of school children in Argentina is likewise to be regarded as a social problem. The internist Prof. Dr. Rafael A. Bullrich recently made an investigation and arrived at the following results: In England and in the Scandinavian countries, the mortality of children from this disease is higher than in other countries (from 3.6 to 4.5 per cent); in the United States it is estimated at 2.41 per cent. In Argentina, according to investigations of Macera and Costa Bertani in Buenos Aires, the mortality from this disease among children up to 15 years of age is 22 per cent; however, in Rosario, the second largest city of Argentina, it is, according to Sloer, 12.5 per cent among children of the ages from 4 to 15 (as it is in France). According to a communication of Senator Landaburi in the Argentine senate, 2.41 per cent of the children less than 14 years of age died as the result of this disease. Bullrich concludes that the ratio of morbidity and mortality of cardio-articular rheumatism of children, taken absolutely, as well as relatively to other infectious diseases, is as high in Argentina as in other countries, if not higher.

Medical Schools in the Argentine Republic

In the Argentine Republic all the universities are supported by the federal government. Of the six universities, four have faculties of medicine. These faculties comprise, besides the medical school, those of pharmacy and dentistry and some of them a school for midwives. There are 8,428 medical students (the population of the country is about 14 million); 545 new doctors graduated in 1939.

The B.A. degree is required for entrance in all the schools; those of Buenos Aires and La Plata also have an entrance examination. The course of studies varies from six to seven

years, two or three of which are preclinical and four clinical. A thesis is also required by the medical school of Buenos Aires; the Rosario school requires a thesis and a course in history of medicine for the doctor's degree but gives a diploma permitting practice without these last requisites. The university diploma in all cases permits practice without further examinations. The number of students makes it necessary for them to take their practical work in large groups; in the preclinical years they attend the laboratories only about once a week. A limitation of the students to the capacity of the schools has often been requested by the professors, but politics has always stopped the measures necessary to put it through. In 1927 the medical school of Buenos Aires decided to limit the number entering but was overridden by the university council. The medical school in La Plata has in theory limited to 100 the number of students entering the first year, but in practice its laboratories and facilities are insufficient even for that number. There are only three full time professors in Buenos Aires, two in Rosario and two in Córdoba. A student may take examinations any number of times; these take place three times a year, so that with sufficient persistence students who are not really capable may graduate. The schools are governed by a council of eight professors elected by the full professors, four elected by the adjoint professors and three students elected by the students. In spite of so many unfavorable circumstances, in recent years there has been an increasing number of students and young doctors. The general welfare of the country has progressed and naturally has had a favorable influence on the universities.

Personals

Dr. J. A. Etchepareorda has been appointed acting director of the national department for hygiene.

The decease of Prof. E. P. Fidanza, who occupied the chair of dermatology at the school in Rosario, is greatly regretted. He was one of the most distinguished and active specialists in the country.

Brief Mention

The Pediatric Society of Uruguay (Sociedad uruguaya de pediatria) has celebrated its twenty-fifth anniversary.

The new anesthetic apparatus of Prof. José Arce has been transmitted to the president of the Royal Society of Medicine in London.

The Comité Franco-Argentino, organized to aid war victims, has presented twenty motorized ambulances to the French Red Cross.

Marriages

BENJAMIN OWEN RAVENEL, Baltimore, to Miss Evelyn Martin of Columbia, S. C., May 24.

JOHN BRISTOL GRAMLICH, New York, to Miss Eleanor Swift of Maplewood, N. J., May 11.

WALTER E. GOEHRING, Blair, Neb., to Miss Edith Cochrane of Butte, Mont., March 25.

ROBERT LEE PERCY, Rochester, N. Y., to Miss Marjorie Nina Rouch of Ontario, May 5.

ROLAND I. PRITIKIN, Chicago, to Miss Jeanne Du Pre Moore of Rockford, Ill., May 25.

GEORGE D. WHITACHE, Springfield, Ohio, to Miss Mary Esther Robson in April.

ROBERT F. KAISER to Miss Marjorie Eileen Ferguson, both of Philadelphia, June 1.

RALPH MOSCHELLA to Miss Helen Holmesley, both of Statesville, N. C., April 8.

SAMUEL RATHBUN, Cleveland, to Miss Mollie McIntyre of Omaha, April 27.

RALPH V. NICOSIA to Miss Ann Sheerin, both of Dayton, Ohio, March 27.

Deaths

Joannes Gregorius Dusser de Barenne, New Haven, Conn.; Universiteit van Amsterdam Geneeskunde Faculteit, Netherlands, 1909; instructor of physiology at the University of Amsterdam from 1909 to 1911; psychiatrist to the Meerenberg Asylum, Holland, from 1911 to 1914; lecturer in physiology at the University of Utrecht from 1919 to 1930; neurologist to St. Antonius Hospital, Utrecht, from 1919 to 1930; since 1930 Sterling professor of physiology at the Yale University School of Medicine; member of the American Physiological Society, American Society for Pharmacology and Experimental Therapeutics, Inc., British Physiological Society and Neurological Society of Amsterdam; on the editorial board of the *Journal of Neurophysiology*; aged 55; died, June 9, in the Deaconess Hospital, Boston, of coronary thrombosis.

William Thomas Coughlin ♂ St. Louis; Washington University School of Medicine, St. Louis, 1901; professor of surgery, St. Louis University School of Medicine; instructor in anatomy at his alma mater from 1901 to 1911; surgeon in chief of St. Mary's Group of Hospitals; consulting surgeon to the Jewish Hospital, St. John's Hospital and the City Hospital; member of the Western Surgical Association and the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; served during the World War; editor of the American edition of Rose and Carless' "Manual of Surgery"; aged 67; died, May 22.

Charles Stover ♂ Amsterdam, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1880; member of the House of Delegates of the American Medical Association in 1908 and 1910; past president of the Medical Society of the State of New York and the Medical Society of the County of Montgomery; city health officer from 1882 to 1889; on the staffs of the Amsterdam City and St. Mary's hospitals; for many years secretary of the Montgomery County Tuberculosis and Public Health Association; at one time secretary of the board of trustees of the New York State Hospital, Ray Brook; aged 89; died, April 9.

Joseph Edwards Kerney ♂ Providence, R. I.; Yale University School of Medicine, New Haven, Conn., 1908; member of the American Urological Association; fellow of the American College of Surgeons; formerly associated with the United States Public Health Service; chief urologist, Rhode Island Hospital, Providence, and the Memorial Hospital, Pawtucket; attending urologist, St. Joseph's Hospital; consultant in urology, Charles V. Chapin and Miriam hospitals, Providence, Westerly (R. I.) Hospital, South County Hospital, Wakefield, and the state institutions, Howard; aged 58; died, May 4, of cerebral hemorrhage.

Henry Holdich Morton ♂ Brooklyn; Long Island College Hospital, Brooklyn, 1882; since 1930 emeritus professor of urology at his alma mater; member of the American Association of Genito-Urinary Surgeons and the American Urological Association; fellow of the American College of Surgeons; on the staffs of the Long Island College Hospital, Kings County Hospital and St. Peter's Hospital; member of the committee on venereal diseases in the Surgeon General's Office during the World War; author of "Genito-Urinary Diseases and Syphilis" in five editions; aged 78; died, May 3, in Gulfport, Fla.

Richard Root Smith ♂ Grand Rapids, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; member of the House of Delegates of the American Medical Association, 1911-1912; member of the American Gynecological Society; a founder and a governor of the American College of Surgeons; served during the World War; on the staff of the Blodgett Memorial Hospital; past president of the Michigan State Medical Society and the Kent County Medical Society; regent of the University of Michigan from 1931 to 1937; aged 70; died, May 7, of coronary thrombosis.

Edward John Angle ♂ Lincoln, Neb.; Medical College of Ohio, Cincinnati, 1887; University of Pennsylvania Department of Medicine, Philadelphia, 1895; member of the American Urological Association and the American Academy of Dermatology and Syphilology; formerly professor of skin and genito-urinary diseases at the University of Nebraska College of Medicine; attending dermatologist to the Lincoln General Hospital and St. Elizabeth's Hospital; consulting dermatologist to the Bryan Memorial Hospital; aged 75; died, April 25.

James Wilson Hunter Jr. ♂ Norfolk, Va.; University of Virginia Department of Medicine, Charlottesville, 1901; fellow of the American College of Physicians; member of the American Roentgen Ray Society, Radiological Society of North America, Inc., and the American College of Radiology; past president of

the Norfolk County Medical Society; served during the World War; on the staff of the Hospital of St. Vincent de Paul; aged 62; died, May 11, in the Army and Navy Hospital, Hot Springs National Park, Ark., of coronary occlusion.

James Morrison ♂ Lynchburg, Va.; University of Virginia Department of Medicine, Charlottesville, 1898; past president of the Lynchburg Academy of Medicine and the Virginia Society of Ophthalmology; on the staffs of the Lynchburg General Hospital, Marshall Lodge Memorial Hospital and Virginia Baptist Hospital, Lynchburg, and the State Colony for Epileptics and Feeble-minded, Colony; aged 68; died, May 15, in the University of Virginia Hospital, Charlottesville.

John D. Miller ♂ Cincinnati; Medical College of Ohio, Cincinnati, 1897; formerly clinical professor of gynecology at the University of Cincinnati College of Medicine; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons; gynecologist to the Good Samaritan Hospital and Christ Hospital; consultant in gynecology at the Cincinnati General Hospital and the Deaconess Hospital; aged 64; died, May 18.

Donald MacKenzie Faulkner, Richmond, Va.; University of Virginia Department of Medicine, Charlottesville, 1918; member of Medical Society of Virginia; associate professor of orthopedic surgery at the Medical College of Virginia; member of the American Academy of Orthopedic Surgeons; on the staff of the Crippled Children's Hospital; aged 47; died, May 6, when he fell from a window.

Joseph Stanley Maleski Miller, Collegeville, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1917; member of the Medical Society of the State of Pennsylvania; served during the World War; on the staff of the Homeopathic Hospital, Pottstown; aged 45; died, April 1, in the Homeopathic Hospital of Chester County, West Chester, of chronic myelogenous leukemia.

Caesar Hirsch ♂ Seattle; Albert-Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1909; member of the Medical Society of the State of New York and the American Academy of Ophthalmology and Otolaryngology; at one time adjunct professor of otology at the New York Polyclinic Medical School and Hospital, New York; aged 54; died, May 14.

William Wallace McKinley, Toronto, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1903; L.R.C.P., of Edinburgh, L.R.C.S., Edinburgh and Licentiate Royal Faculty of Physicians and Surgeons of Glasgow, 1908; formerly chairman of the school board of Port Hope; aged 66; died, April 21, in the Toronto General Hospital.

Otis Burgess Spalding ♂ Lieutenant Commander, U. S. Navy, San Diego, Calif.; Cooper Medical College, San Francisco, 1898; entered the navy in 1921 and retired Jan. 1, 1940, because of ill health; fellow of the American College of Physicians and the American College of Radiology; aged 64; died, April 12, of hypertensive heart disease.

Harold Ney Prothero ♂ Jeannette, Pa.; Jefferson Medical College of Philadelphia, 1903; past president of the Westmoreland County Medical Society; member of the school board; veteran of the Spanish-American War; on the visiting staff of the Westmoreland Hospital, Greensburg; aged 61; died, April 24, of coronary thrombosis.

Alexander Roderick McDonald ♂ Chicago; Chicago Homeopathic Medical College, 1897; Rush Medical College, Chicago, 1898; at one time professor of physiology at the Hahnemann Medical College and Hospital; aged 77; on the staff of the West Suburban Hospital, Oak Park, Ill., where he died, May 3.

Byron Walter Malfroid ♂ Flint, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1918; fellow of the American College of Surgeons; served during the World War; on the staffs of St. Joseph's Hospital, Women's Hospital and the Hurley Hospital; aged 46; died, April 6.

Maximilian Edward Smukler, Philadelphia; Jefferson Medical College of Philadelphia, 1910; member of the Medical Society of the State of Pennsylvania; ophthalmologist to the bureau of health of Philadelphia; on the staff of the Northern Liberties Hospital; aged 51; died, April 23.

Arnold William Hackfield ♂ Seattle; University of Michigan Medical School, Ann Arbor, 1927; member of the American Psychiatric Association; served during the World War; on the staffs of the United States Marine Hospital and the King County Hospital; aged 40; died, April 26.

Otis L. Aultz, Charleston, W. Va.; College of Physicians and Surgeons, Baltimore, 1891; member of the West Virginia State Medical Association; past president of the Kanawha

County Medical Society; at one time city health officer; aged 71; died, May 14, of arteriosclerosis.

Alva Nicholas Collins * Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1885; past president of the Wayne County Medical Society; on the consulting staff of the Harper Hospital; aged 79; died, May 23, of coronary sclerosis and thrombosis.

Andrew Jackson Jones, Highland Home, Ala.; Kentucky School of Medicine, Louisville, 1885; member of the Medical Association of the State of Alabama; for many years postmaster; past president of the Crenshaw County Medical Society; aged 82; died, April 7.

Charles David Mason, Eutaw, Ala.; University of Alabama School of Medicine, 1914; member of the Medical Association of the State of Alabama; aged 53; died, May 17, in the Veterans Administration Facility, Tuscaloosa, of injuries received in an automobile accident.

John Johns, Martins Ferry, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1902; member of the Ohio State Medical Association; formerly member of the city board of education; health officer; aged 63; died, April 14.

Lincoln Atwood Sukeforth, Duluth, Minn.; Medical School of Maine, Portland, 1886; member of the Minnesota State Medical Association; aged 79; died, April 7, of arteriosclerosis, hypertensive heart disease and bronchopneumonia.

Walter Linwood Watson, Monroe, Maine; Medical School of Maine, Portland, 1894; Bellevue Hospital Medical College, New York, 1894; aged 72; died, March 20, of carcinoma of the stomach, right kidney and prostate.

Joseph F. Plynt, Paris, Mo.; Marion-Sims College of Medicine, St. Louis, 1892; Missouri Medical College, St. Louis, 1899; member of the Missouri State Medical Association; aged 71; died, May 3, of pneumonia.

Walter Joseph Smith, New York; Albany (N. Y.) Medical College, 1913; served during the World War; aged 58; died, April 25, in the Fairview Hospital, Great Barrington, Mass., of cerebral hemorrhage.

May Elizabeth Walker, Piedmont, Calif.; Cornell University Medical College, New York, 1914; on the staff of the Peralta Hospital, Oakland; aged 60; died, April 26, of carcinoma of the lung and breast.

John Jeurink, Denver; Barnes Medical College, St. Louis, 1899; member of the Colorado State Medical Society; aged 73; died, May 9, in St. Luke's Hospital of diabetes mellitus and arteriosclerosis.

Guy Llewellyn Burritt, Harrington, Maine; Baltimore University School of Medicine, 1901; member of the Maine Medical Association; aged 71; died, April 30, of cardiac thrombosis.

Herbert Ashley Church, East Canaan, Conn.; New York Homeopathic Medical College and Hospital, New York, 1889; died, April 6, of arteriosclerotic heart disease and bronchopneumonia.

Jesse Wilbur Calkins, Oakland, Calif.; Denver and Gross College of Medicine, 1907; member of the Pacific Coast Ophthalmological Society; aged 60; died, April 22, of coronary embolism.

Royce Lee Love, De Ridder, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1903; member of the Louisiana State Medical Society; aged 62; died, March 30.

Lucius Barnes Goodyear, Dixon, Ill.; Physio-Medical College of Indiana, Indianapolis, 1894; served during the World War; aged 76; died, May 1, of a self-inflicted bullet wound.

Wendall Doop Smith, Bridgton, Maine; University of Oklahoma School of Medicine, Oklahoma City, 1932; aged 36; died, April 6, of a self-inflicted bullet wound of the mouth.

Edgar Valentine Trull, Manchester, Vt.; Albany (N. Y.) Medical College, 1874; member of the Vermont State Medical Society; aged 85; died, April 23, of chronic myocarditis.

Joseph Charles Tripp, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1894; aged 69; died, March 22, of carcinoma of the prostate and bladder.

C. W. Gillham, West Point, Ill.; Homeopathic Medical College of Missouri, St. Louis, 1897; aged 67; died, May 2, at St. Mary's Hospital, Quincy, of pneumonia.

James Francis Hennessey, Stamford, Conn.; College of Physicians and Surgeons, Baltimore, 1904; aged 62; died, April 11, of arteriosclerosis and heart disease.

Beauregard F. Flint, Orange, Calif.; Eclectic Medical Institute, Cincinnati, 1886; aged 78; died, April 7, of hypostatic pneumonia and chronic myocarditis.

Nathaniel Love, Elmira, N. Y.; University of the City of New York Medical Department, 1889; aged 81; died, March 10, of acute dilatation of the heart.

Walter Ceasey Kissinger, New Castle, Pa.; Jefferson Medical College of Philadelphia, 1903; aged 60; died, March 20, of a self-inflicted bullet wound.

William Charles Wright, Buffalo; Jefferson Medical College of Philadelphia, 1884; aged 78; died, March 23, of cerebral hemorrhage and hypertension.

Robert John Beacom, Killingly, Conn.; University of Edinburgh Faculty of Medicine, Scotland, 1886; aged 78; died, April 14, of chronic myocarditis.

William Edmund Cecil Day, Sioux Lookout, Ont., Canada; University of Toronto Faculty of Medicine, 1908; aged 56; died, March 30.

Bureau of Investigation

WORTHLESS (trademark) "CURES" DECLARED FRAUDULENT

Post Office Bars Yosmrite Nabona's "Indian" Stuff from the Mails

A picturesque career in quackery has been closed—or at least halted—by the issuance of two Post Office fraud orders against a "healer" calling himself variously "Dr. Yosmrite Nabona" and "Rev. Yomachee."

In April 1929 a Colorado Springs (Colo.) paper carried a full-page advertisement of Nabona's "Navajo Indian Remedies Co., Inc.," located in what was described as "The Navajo Indian village on the edge of the Black Forest" some 14 miles from Colorado Springs. In this advertisement Nabona, claiming to be known as "The Indian Doctor . . . all over the United States and in many foreign countries," declared that some \$60,000 had been spent in recent months and as much more would be spent in that year in developing the village; that "as many as 700 patients have been treated in a single day," and that several Navajo Indian families were associated with him, compounding his various "remedies," this task being "an adjunct of the modern laboratory" that he claimed to have there.

Nabona further declared that since the previous summer (1928) "a veritable path was beaten to his door in the forest." But prior to that time, if one could believe his story, he was

flat broke, having gone thru the Florida hurricane where his sanatorium was literally blown away and his real estate holdings in Miami and Miami Beach destroyed. However, he started over in the Pike's Peak region and after indifferent success for a time in Manitou hit upon the idea of locating in the Black Forest . . .

Nor did Nabona's colorful story stop there:

A soldier of fortune for many years, Dr. Nabona has had a wide and varied experience having traveled to practically every corner of the globe in his quest of adventure. Born of full blooded Navajo Indian parents on a government reservation at Red House, Ariz., he was left "on his own" at the age of 9 when his parents died. For a few years he lived with a German couple in the Panhandle of Texas. He removed with them to their home in Germany and there came under the notice of a prominent Berlin surgeon. The Indian youth applied his knowledge of bone setting learned from his Indian parents to reset a broken leg of the son of the surgeon. For this act the surgeon guaranteed his education in the medical schools of Berlin and Madgeburg, [sic] Germany. He was graduated from the medical department of the University of Berlin.

Just prior to the outbreak of the Spanish-American war Nabona came back to this country and when hostilities were declared joined the United States navy, seeing duty on the U. S. S. Baltimore under Admiral Dewey during the famous battle of Manila. Following the conclusion of the Spanish-American war his wandering saw him in service with the Boers in South Africa, as a member of the French Foreign legion in northern Africa, then a period in the Mexican navy which he joined at Guaymas. He later traveled in South America and finally in India.

It was in Calcutta that Dr. Nabona learned the arts of the native Hindu medicine men and their practices he still follows to a great extent. The doctor has the features of the native Navajo Indian but speaks perfect English with a decided German accent, the result of his long life with the Germans and education in Teutonic educational institutions.

With this alleged learned background Nabona might have been expected to take his place in the scientific world rather than to run a mere "patent medicine" business and a quack "sanatorium." But apparently he had his own reasons for choosing the latter, and that he prospered in it is evident, if one may believe his boast that "hundreds of orders are received daily by mail and telegraph, from patients all over the United States and foreign countries for the Navajo Indian Remedies."

Nor did Nabona hesitate to disclaim any unworthy motive:

We are not here to defraud the people [Italics ours—Ed.] but to build up a thriving industry comparable to many others of similar nature throughout the country.

The Post Office Department, however, held a different opinion of this matter. Nabona further claimed:

If I wanted to bunco the public as many think I am doing, I could have done it long ago. With a few mysterious rites and ceremonies, judicious use of paint and blankets, I could have cleaned up a million dollars in less than a year and left.

There were reports that Nabona sometimes "diagnosed" ailments by examining a drop of the "patient's" blood, which suggests that he was following the old Albert Abrams "elec-

tronic" fakery, as some observers charged and as will be brought out later. At any rate, he was said to have treated such serious diseases as cancer and tuberculosis. In a booklet that he put out under the title "A Treatise on Health and Happiness" he listed a long array of "cures," mostly designated as "Units," for various disorders but in another part of the booklet cautiously stated that "In order to comply with the regulations of the Food and Drug Administration . . . we shall not employ the following list of names of diseases in connection with our medicinal preparations." There followed a column of twenty-three ailments (plus "etc."), among them cancer and tuberculosis (as well as "consumption"). In other words, he seems to have "put over" at home what he later did not dare claim on his labels.

An exhaustive search through the records of the American Medical Association failed to reveal that Nabona had ever been graduated by or had even attended any medical school in this country or abroad or had been licensed to practice medicine in any state in the union on the basis of any diploma issued by either an American or a foreign medical college. They do show that when Nabona learned that the Colorado officials were about to investigate his activities he attempted to

obtain a license to practice medicine in that state by producing an alleged diploma which he claimed to have received in 1896 from the University of Berlin. A photostat of this "diploma" was translated by an expert, who pronounced it to be spurious, and shortly afterward the University of Berlin reported that it had never issued a diploma to Nabona in the period from 1896 to 1910 or even enrolled him as a student, so far as it could find.

Although the Colorado authorities in 1929 also turned down Nabona's application for a license to conduct his "sanatorium," it was said that he continued his activities around

Reproduced from one of Nabona's booklets.

Colorado Springs for several years. In March 1932 Nabona advertised in a Pueblo, Colo., paper that he had located in Long Beach, Calif., and would treat his Colorado patients by mail, the Colorado courts having taken "everything" from him for alimony and attorneys' fees. The California authorities reported that Nabona had various diplomas exhibited on his walls at Long Beach. One was from the "College of Divine Metaphysics, Indianapolis" dated Jan. 15, 1932, conferring on him the degree of "Doctor of Metaphysics," and another from the same institution giving him the degree of "Doctor of Psychology." The report further stated that Nabona claimed that these diplomas cost him \$150.

There was also a "duplicate" certificate from the Illinois College of Chiropody, certifying that Nabona had attended a course of lectures and a clinic from Aug. 23 to Sept. 3, 1920. Another document on exhibit appeared to be a diploma from the "Universitat von Berlin" (University of Berlin) dated December 1896, and supposedly conferring on Nabona the degree of "Doctor of Medicine and Massage." This was the diploma that had previously been declared spurious by the Colorado authorities when he attempted to obtain a license to practice in that state. Again, there was a "Certificate of Dissection, Department of Anatomy, National College of Chiropactic, Chicago." Finally there was a photograph of Albert

Abrams' class of 1923, showing Nabona as No. 23 in the class and giving his address as Sarasota, Fla. On his desk Nabona had a booklet calling him "Dr." The California authorities felt that his unwarranted use of this title was the only thing they could legally object to, particularly as Nabona apparently thought it expedient to comply with the state laws before starting business in Long Beach. They warned him, however, to discontinue using the title "Dr." and to remove it from all copies of his booklet.

In July 1933 a Denver paper was quoted as saying that Nabona had recently been arrested in Arizona and was to be deported on the ground that he was not an Indian but a German and had entered this country illegally. In June 1934 practically the same information came from Washington, D. C., but apparently the deportation proceedings were dropped. In July of that year Nabona sent out a letter over his signature, on the letterhead of the Navajo Industries Co., on which the Long Beach, Calif., address was crossed out and a postoffice box in Washington substituted. In this letter, addressed to a woman in Illinois, Nabona stated: "I am here on business and will be for some time." He went on to tell the woman that he "would not advise an operation" in her case "as the same will always come back" and suggested instead that she "send for two Units for your condition, the same is a two months treatment and the price is \$4.00." Thus it appears that even while under the scrutiny, if not actually in the custody, of the government, Nabona was still promoting his quackery.

About this time the government also commenced action against Nabona through another agency. The Department of Agriculture seized in interstate commerce quantities of "Navajo Indian Herbal Teas" that had been shipped by Navajo Industries Co., Inc., and Paul Anacker, alias Dr. Yosemite Nabona, on or about March 28, 1933. It was charged that the labels bore false and fraudulent claims. Analyses by government chemists were said to reveal that the various products consisted chiefly of cut dried herbs, essentially as follows: For asthma, elder flowers and coltsfoot; for "hardening of the arteries," yarrow and horsetail; for neurasthenia, camomile, lavender and mint; for stomach catarrh, yarrow, elder, camomile and mint, and the one designated loosely for "stomach trouble" was essentially fenugreek and aloe.

On Nov. 21, 1934, a jury found the defendants guilty on all counts and the court imposed a fine of \$200 against the Navajo Industries Co., Inc., and \$200 against Yosemite Nabona (alias Paul Anacker) on one count of the information, arresting judgment on the remaining five counts. On December 5, Nabona was placed on probation for two years on condition that he pay the fine within that period.

Shortly afterward (Jan. 20, 1935) the United States Department of Agriculture issued a release to newspapers on this case, reading as follows:

Paul Anacker, better known to swindled thousands as Dr. Yosemite Nabona, who "adopted" himself into the Navajos of Colorado, is in the toils of the law again. He was fined \$200 in the Federal court at Los Angeles, Calif., recently. In default of fine, he was remanded to jail. Operating from Long Beach, Calif., where his outfit was called "Navajo Industries, Inc.," and formerly from Colorado Springs, Colo., where he was known as the "Navajo Indian Remedies Co., Inc." Anacker had shipped various herbs, powders, pills, and liquid medicines which were in violation of the Federal Food and Drugs Act.

Investigation by Federal inspectors prior to the trial had indicated that "Dr. Nabona," who posed as an American Indian, was in reality a German by birth, and that he sent money at fairly regular intervals to a person, Frieda Anacker, in Germany. Although he listed in his advertising booklets a hundred diseases, including Bright's disease, pneumonia, syphilis, arthritis, epilepsy, paralysis and tumors, "Doctor" Nabona's sole claim to diagnostic and professional ability rested upon a "diploma" purporting to come from the University of Berlin, which, when translated, proved to be a midwife's certificate.

Before his case came to trial, Anacker's trail had led across the country and back. He changed his place of business from his original location at Colorado Springs, Colo., to Los Angeles, but the earthquake of March 1933 interrupted his prosperity there. He went to Tucson, Ariz. He was later arrested at El Paso, Tex., on suspicion of illegal entry, but was released. In an attempt to vindicate himself, he visited the Indian Bureau and the Department of Labor in Washington, D. C., and then camped for several weeks at a tourist camp near Berwyn, Md., selling Indian wares and his own medicines. There he was again arrested and returned to California for trial.

But though it is reported that Nabona lay low for a while after this prosecution it was to be expected that he would

bob up again with some fakish scheme. When he did, still another government agency, the Post Office Department, began to investigate him on finding that he had been operating since 1936 under two new names, Ajna Indian Herb Co. and Ajna Indian Preparations, at Hot Springs National Park, Ark. The trademark "Worthless," which they used on their mail-order nostrums, presumably represents unconscious humor and recalls the Minnesota woman who years ago put out something she called "Humbog Oil."

The Post Office memorandum which recommended that a fraud order be issued against Nabona's outfit brought out that though Nabona represented his products as being "herbal" mixtures and actual Indian remedies, some of them were, in fact, composed of milk sugar and small amounts of mineral substances, and all were purchased from pharmaceutical concerns in New York and Missouri. It was shown in one case that an individual claiming to have a femoral hernia sent Nabona an order for a treatment on the strength of a testimonial that Nabona had published on a similar case. The man made it clear that he did not want the treatment *unless* it would heal his hernia. Nabona accepted his money and sent the "treatment," but his letter as quoted in the memorandum more or less dodged the question of a *cure*. Government chemists reported that the tablets Nabona sent the man were essentially milk sugar and small traces of minerals including phosphorus, chloride, iron, sodium, potassium and arsenic. And this mixture, according to one published testimonial, was supposed to have cured a hernia! Further, the government brought out that the thing was essentially identical with some tablets that Nabona sent out, with a herbal mixture of tansy, strawberry and huckleberry leaves, as a remedy for diabetes! Almost identical tablets were sent out by Nabona for high blood pressure. There were also some other nostrums in the category.

The Post Office memorandum charged that the sale of Nabona's products through the mails constituted a fraud and recommended that they be debarred. Nabona neither appeared at the hearing to defend himself nor sent any one to represent him. On July 24, 1939, a fraud order was issued against "Dr." Yosemite Nabona, Ajna Indian Herb Co., Ajna Indian Preparations and their officers and agents as such.

But Nabona, apparently hoping to outsmart the Post Office, moved to Milwaukee, adopted the name "Rev. Yomachee" and again engaged in the activities that had brought on the order against his Arkansas business. He even admitted to one inquirer that the preparations he was sending out from Milwaukee were the same as those he had sold from Arkansas and solicited an order for his "rupture cure" tablets. Consequently on Sept. 29, 1939, a supplementary fraud order was issued to cover the name "Rev. Yomachee."

Thus far Nabona's record in quackery! Would it be surprising if he were to bob up again with the same old frauds but under still another trade style?

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Dormalgin.—Lawson M. Luth, Darien, Conn. Composition: In each tablet approximately 2 grains of aminopyrine and three-fourth grain of a barbituric acid derivative. For rheumatism, gout, lumbago, sciatica, neuritis, painful menstruation and toothache. Fraudulent therapeutic claims.—[N. J. F. D. 30782; January 1940.]

E E Powders.—E E Medicine Co., Greenville, S. C. Composition: 4.99 grains of acetanilid per powder. Misbranded because labeled to contain only 4 grains of acetanilid per powder.—[N. J. F. D. 30881; January 1940.]

Hed Klear.—Van Patten Pharmaceutical Co., Chicago. Composition: Volatile oils including eucalyptus and menthol, with grain alcohol, isopropyl alcohol, acetone and water. Fraudulently represented as a relief for head colds, rhinitis, sinus irritation, hay fever and nasal catarrh.—[N. J. F. D. 30879; January 1940.]

Menestrex.—Rex Laboratory, Nashville, Tenn. Composition: Quinine sulfate (3.8 grains) and potassium permanganate (0.8 grain) per capsule. Fraudulently represented as a menstrual regulator.—[N. J. F. D. 30777; January 1940.]

Peranol.—Peranol Products, Chicago. Composition: Volatile oils including eucalyptus, camphor and menthol, with about 21 per cent of alcohol. For hay fever, nasal catarrh and rose fever. Fraudulent therapeutic claims.—[N. J. F. D. 30884; January 1940.]

Sodasal.—Sodasal Laboratories, Detroit. Composition: Aminopyrine (about 8 grains per fluid ounce), sodium salicylate (33.5 grains and 15 grains respectively, in two specimens), baking soda, sugar and water. Fraudulently represented as an effective alkaline treatment and a remedy for rheumatic pains, lumbago, uric acid and some other things.—[N. J. F. D. 30895; January 1940.]

Ung Nigrum.—U. N. Laboratories, Seattle. Composition (by percentages): Silver nitrate, 5.25, mercury, 3.35 and phenol, 1.68. Fraudulently represented as a remedy for burns, fresh or infected wounds, ulcers and infectious skin diseases.—[N. J. F. D. 30790; January 1940.]

U. N. Rectal Cones.—U. N. Laboratories, Seattle. Composition: Silver nitrate (0.015 Gm.), mercury (0.062 Gm.) and cocoa butter. Fraudulently represented as an effective treatment for internal hemorrhoids, fissures or rectal inflammation.—[N. J. F. D. 30790; January 1940.]

U. N. Vaginal Cones.—U. N. Laboratories, Seattle. Composition: Silver nitrate (0.1 Gm.), mercury (0.02 Gm.) and gelatin. For "pelvic inflammation, trichomonas and all vaginal infections." Fraudulent therapeutic claims.—[N. J. F. D. 30790; January 1940.]

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

RESUSCITATION OF SUBMERGED PERSONS

To the Editor:—A boy aged about 17 had been in the water between an hour and a half and two hours before the body was brought to the surface. Artificial respiration was started as soon as he had been placed on the bank, with the use of an H-H inhalator with carbon dioxide-oxygen mixture but with no respiratory excursion. Even froth from the mouth was not obtained. There were no obstructions that could be determined. I injected 1 cc. of solution of epinephrine hydrochloride directly into the heart with no response. As there was no respiratory exchange and considering the fact that he had been in the water so long and had not responded to the epinephrine hydrochloride, I pronounced him dead with no hope of resuscitation, after about twenty minutes. In the crowd which always gathers at such an event, some of the spectators criticized the fact that we did not continue longer, stating that they had known of resuscitation after three hours' immersion. I want to obtain data as to the length of time a person can be submerged and yet be resuscitated. It has always been my impression that no one has ever been revived who has been in the water more than thirty minutes. In another method of artificial respiration of which I have heard that is considered to be better than the Schafer prone method there is manipulation of the shoulders. I would appreciate any information you have on these questions.

Charles W. May, M.D., Pasco, Wash.

ANSWER.—Successful resuscitation of human beings has been reported to have been obtained after twelve, fifteen and twenty minutes and even from one-half to three hours from the time of initial submersion in water to the institution of resuscitative measures. The reliability of such reports, however, especially those recording the more prolonged periods, is subject to question. In the absence of actual timing by a watch or clock it is only natural, because of the confusion and anxiety incident to drowning, for observers to tend to overestimate the time.

The period after initial submersion during which resuscitation can successfully be applied will vary from case to case, depending on, among other things, the individual himself, the circumstances under which submersion occurred, whether he was able to take partial breaths of air, how much water was taken into the lungs and respiratory passages and, at least to some extent, the efficiency of the method of resuscitation employed. The power of an individual to remain under water without breathing varies considerably and is somewhat improved by practice. Ability to do so for a period of four minutes and forty-six and one-half seconds has been referred to (Resuscitation After

Drowning, *Queries and Minor Notes*, THE JOURNAL, Aug. 29, 1908, p. 779). In general, attempts to resuscitate persons seemingly dead from drowning are more successful with those who become unconscious immediately on falling into the water and with those in whom apparent death occurs with little struggle. This is because the effect of submersion in water depends on whether the individual remains conscious and attempts to breathe or whether, owing to syncope, shock, apoplexy, spasm of the glottis or the like, breathing ceases immediately, in which case little or no water will be taken into the lungs. Power of recovery from apparent death from drowning then is in inverse proportion to the amount of water and mucous froth in the air passages and to the penetration of the substance of the lung with water, which amount and penetration, in general, are proportional to the efforts made at self preservation (Taylor's Principles and Practice of Medical Jurisprudence, ed. 9, edited by Sydney Smith, with revision of legal aspect by W. G. H. Cook, London, J. & A. Churchill, Ltd., 1934, vol. 1, p. 612). If the air passages are filled with water and froth and the lungs are waterlogged, resuscitation will be impossible no matter how soon the body is removed.

Observations on dogs by the Medico-Chirurgical Society of England (Report on Suspended Animation, *M.-Chir. Tr.*, 1862, p. 449. Taylor's Principles and Practice of Medical Jurisprudence, vol. 1, pp. 609, 611-612. Glaister's Medical Jurisprudence and Toxicology, ed. 6, edited by John Glaister, Baltimore, William Wood & Co., 1938, chapter 7, pp. 149-150) showed that complete submersion for a minute and a half was fatal provided respiratory effort was made while submersion was complete, but when respiration was entirely suspended under water simple deprivation of air could be maintained for four minutes without necessarily fatal results. Pol N. Coryllos (Mechanical Resuscitation in Advanced Forms of Asphyxia: A Clinical and Experimental Study in the Different Methods of Resuscitation, *Surg., Gynec. & Obst.* 66:698 [April] 1938, p. 712), after similar observations, reported that the whole phenomenon of asphyxia by submersion "from its beginning to the death of the animal presented a remarkably constant duration of four to five minutes." He demonstrated four distinct phases of asphyxia by drowning, each of which lasted about one minute: (1) initial apnea, (2) dyspnea, (3) terminal apnea characterized by arrest of respiration, drop of blood pressure and disappearance of reflexes and muscular tonus, and (4) phase of arrest of the heart, characterized by rapidly progressing weakness of cardiac contraction and arrest of the heart. He found that resuscitation, while still easy when submersion was interrupted at the beginning of the third phase of asphyxia, became increasingly difficult as the end of that phase was approached. In the case of one dog, submersion was interrupted at the end of the third phase but asphyxia progressed to the fourth phase, the heart stopped, and resuscitation by artificial respiration and bronchoscopic intratracheal insufflation was unsuccessful. Another dog under the same conditions gave no response to artificial respiration but the animal was brought back to life by a mechanical resuscitator within twenty seconds after its application.

As a general rule in human beings asphyxia supervenes from one to two minutes after submersion or, at the most, three or four minutes, and death characterized by cessation of the heart usually occurs before the expiration of five or six minutes, but life may be considerably prolonged if from any cause water has been prevented from entering the lungs (Dolley, D. H.: On Resuscitation, *Univ. Missouri Bull., M. Ser.* 1:5 [Oct.] 1913, on pp. 12-13. Smith, A. J., and Lucke, B. H., in Legal Medicine and Toxicology by Many Specialists, ed. 2, edited by Peterson, Haines and Webster, Philadelphia, W. B. Saunders Company, 1923, vol. 2, p. 380). Smith and Lucke state that the entire process may be completed in three or four minutes or may be prolonged to two or more times this period. They (Legal Medicine and Toxicology by Many Specialists, p. 386) also state that while instances of successful resuscitation have been recorded after submersion for twenty or thirty minutes there is usually little hope of success after submersion for more than four or five minutes; and where asphyxiation has been general and much water has entered the respiratory passages in the wild struggle for life, attempts to revive almost always fail. It is possible for ten or twelve minutes to elapse during "drowning," as partial breaths of air may be taken by the person before he goes down the traditional third time (Drowning and Resuscitation, *Queries and Minor Notes*, THE JOURNAL, Feb. 25, 1939, p. 764). It is probable that absolutely complete submergence for ten minutes, and perhaps less, may so far impair the respiratory center or bring the heart so completely to a standstill as to make the possibility of resuscitation unlikely, and when persons are resuscitated after

being in the water from fifteen to twenty minutes it is probable that submergence was incomplete and that some partial breaths of air were obtained (Drowning and Resuscitation, *Queries and Minor Notes*, *THE JOURNAL*, Oct. 18, 1924, p. 1263; Resuscitation, *ibid.*, Jan. 2, 1926, p. 58). In connection with persons overcome by mine gases it has been reported that deprivation of oxygen for about ten minutes may injure irremediably some of the most essential nerve cells of the brain (Cannon, W. B.; Crile, G. W.; Erlanger, Joseph; Henderson, Yandell, and Meltzer, S. T.: Report of the Committee on Resuscitation from Mine Gases, Technical Paper 77, Department of the Interior, Bureau of Mines, 1914, p. 7). Albert H. Miller (Resuscitation, *Rhode Island M. J.* 15:39 [March] 1932, p. 42) states that resuscitation, to be efficient, must be begun within half an hour from the time when the heart beat ceases. He gives the following periods of resistance to entire deprivation of oxygen for various tissues of the body: cerebrum eight minutes, cerebellum thirteen minutes, medullary centers from twenty to thirty minutes, spinal cord from forty-five to sixty minutes, sympathetic ganglions one hour and mesenteric plexus three hours. Gordon Bates, R. E. Gaby and Wills MacLachlan (The Need for Prolonged Artificial Respiration in Drowning, Asphyxiation and Electric Shock, *Canad. M. A. J.* 39:120 [Aug.] 1938) state that "it is possible for a person to have been under the water for up to half an hour and still live." Their opinion is based on, among other cases, three reported by Canadian physicians and one reported by the American Red Cross, in which resuscitation was successful after the body had been in water respectively for thirty minutes, from twenty to thirty minutes, fifteen minutes and from thirty-two to thirty-five minutes. But according to Taylor's Principles and Practice of Medical Jurisprudence (vol. 1, p. 612) "there can, however, be no question but that the earlier or more loosely recorded cases of recovery after submersion for more than seven to eight minutes involve a fallacy somewhere (possibly some air was drawn down in the clothes or hair of a woman or in the sail of an overturned boat, etc.)."

ATTACKS OF PARA-UMBILICAL PAIN

To the Editor:—A white boy of 7, moderately well nourished, has been having attacks of colicky pain in the umbilical region every few months since the age of 4. These attacks last from a few minutes to a few hours and he has accompanying vomiting. No elevation of temperature is present. During the attacks the umbilical region is quite tender. He has had various diagnoses by varying physicians. Four months ago when I was first called he was in the midst of the longest attack he had had up to that time, the attack having lasted about twenty-four hours. The condition was as described. Exploratory laparotomy disclosed two intussusceptions present in the lower ileum about 3 feet from the ileac junction, the intussusceptions being about 2 feet apart. Reduction was simple. The appendix was normal but was removed. The rest of the small bowel was normal. There was moderate enlargement of the mesenteric lymphatic glands but this was attributed to toxic absorption from the intestinal obstruction. Recovery from the operation was uneventful. Since the operation there have been about two attacks a month lasting a few minutes and one lasting six hours. When calcium gluconate was administered intravenously and atropine sulfate subcutaneously at the onset of the attack on two occasions, the attacks ceased immediately but the aforementioned medication given late in the attack has had no effect. Enemas and abdominal massage have no effect. The child is of rather a nervous type. The attacks usually come in the early evening or night and are more prone to appear following a strenuous day of play or excitement. At present he is taking phenobarbital in small divided doses and tincture of belladonna. A high caloric diet has been prescribed. Any suggestions you may be able to give me with regard to treatment of the attacks or in prevention will be greatly appreciated, as I have been able to find nothing relative to recurrent intussusception of the small intestine in the literature I have available. Dean J. Darius, M.D., Pine Ridge, S. D.

ANSWER:—Recurrent para-umbilical pain may be due to a number of intraperitoneal or retroperitoneal conditions. In young children, congenital anomalies of the small or large bowel frequently produce abdominal pain. A short mesentery may result in transient episodes of volvulus, but there is usually vomiting associated with the pain. A redundant sigmoid may kink or produce para-umbilical pain. Although an exploratory laparotomy failed to reveal any such anomaly in this patient, a complete gastrointestinal x-ray examination is indicated. Chronic recurrent intussusception may be due to tumors, peritoneal adhesions, Meckel's diverticulum, mesenteric cysts, or a ring of polyps in the ileum. The intussusception may be so mild that vomiting, a palpable tumor, and blood in the stools may all be absent. Diagnosis can be made only by careful examination of the bowel during an exploratory laparotomy. The extraperitoneal conditions most frequently causing abdominal pain include diseases of the lumbar vertebrae or of the genito-urinary tract or gallbladder. X-ray examination of the spine, urinalysis, and an intravenous pyelogram are indicated. If all these examinations are negative, the role of allergy must be considered as a possible explanation for para-umbilical pain.

OBESITY AND SCANTY MENSTRUATION AFTER MUMPS

To the Editor:—What would you advise in the way of treatment for the following case? A married woman aged 28, 5 feet 8 inches (173 cm.) in height, weighing 152 pounds (69 Kg.) had severe mumps, bilateral, in December 1938, with some lower abdominal pain. Following recovery her menstrual periods have been regular, of twenty-eight day type but the flow is scanty where previously it was abundant and lasted for from seven to nine days. Now the flow lasts only from one to two days. Also following her recovery from mumps she began gaining weight and has continued to gain in spite of being on a strict diet of 1,500 calories. She has gained 30 pounds (13.6 Kg.) since December 1938. There has been a progressive increase in the amount of fat about the pelvis over the trochanters with some increase over the upper arms and about the spine of the scapula. The remainder of her body appears free of excess fat. Physical examination reveals a temperature of 97 F., pulse 80 systolic, blood pressure 102, thyroid of normal size, basal metabolic rate normal (—2), urine and blood normal and blood sugar normal. General examination is otherwise negative except for the fat deposits described.

M.D., Minnesota.

ANSWER:—This woman apparently had bilateral oophoritis complicating mumps, which is probably of more frequent occurrence than has been recognized. There is no reason why this complication should not occur just as frequently in women as orchitis does in men with mumps. The fact that she menstruates every twenty-eight days is not a criterion of normal function. The decrease in the duration of menstruation of from seven to nine days to one to two days is evidence of decreased ovarian response or ovarian hypofunction.

The gradual gain of 30 pounds has been described as of girdle location except for the trochanteric obesity. Trochanteric padding is characteristic for ovarian hypofunction, especially after 28 to 30 years of age. The patient evidently has a combination of two types of obesity, the girdle type (hypopituitary) and the trochanteric (hypogonad). That she gains weight on a strict 1,500 calory diet is evidence that it is not due to excess intake of food and decreased output. The patient is not much overweight at present, for the average weight for a woman aged 28 and 5 feet 8 inches in height is approximately 142 pounds (64 Kg.). However, there is a possibility that she will continue to increase in weight if measures other than diet are not utilized. Since the physical and laboratory examinations are negative, it is reasonable to suppose that her condition is endocrine in nature.

The causative basis for the ovarian hypofunction may be (1) insufficient gonadotropic hormone of the anterior pituitary to stimulate normal ovarian response, (2) sufficient gonadotropic hormone but inability of the ovary to respond to normal stimulation, and (3) hypofunction of both the anterior pituitary and the ovary.

It seems reasonable to believe from the history of mumps that the condition has more of a hypo-ovarian basis than pituitary; the trochanteric obesity also favors this deduction. However, if the patient really has some pituitary type obesity, then one must bear this in mind.

Without having seen or examined the patient, the best suggestion for treatment that one can give is the administration of 2,000 international units of estrone (theelin) in oil intramuscularly every other day for three weeks following cessation of menstruation. Then discontinue the medication to allow menstruation to occur. Repeat for three or four months. The patient should not be promised too much; if the ovaries are permanently damaged she will probably need substitutive therapy irregularly until after the climacteric.

If the posterior pituitary hypofunctions (the posterior pituitary is probably the gland involved in pituitary obesity) it may be necessary later to administer proper dosages of solution of posterior pituitary.

There is also the possibility of more generalized glandular hypofunction developing, especially involving the thyroid.

GRANULOMA INGUINALE

To the Editor:—What might one expect from curettage of the lesions of granuloma inguinale? This procedure has no doubt been employed in the past and presumably without benefit or it would be in common use. My reason for asking is that I am trying curettage with medicated dressings and don't wish to subject patients to curettage alone as controls, if this can be avoided. Please give me any available information or references.

M.D., Florida.

ANSWER:—Little benefit should be expected from curettage of the lesions of granuloma inguinale. It is more likely to be harmful than beneficial. Careful cleansing and sterile dressings are indicated. Antimony compounds are said to be specific (McGlinn, J. A.: *Am. J. Obst. & Gynec.* 12:665 [Nov.] 1926). A 1 per cent boiled solution of sodium and potassium antimony tartrate is given intravenously. The first dose should be from 0.01 to 0.02 Gm. Thereafter from twelve to fifteen doses are given on alternate days in increasing doses up to

0.12 or 0.15 Gm. Diathermic fulguration has been used by F. G. Greenwood (*Brit. J. Radiol.* 4:488 [Oct.] 1931). Hazen, Howard, Freeman and Scull (*THE JOURNAL*, Oct. 22, 1932, p. 1410) say "while irradiation is reasonably effective, the most certain results are obtained by a freshly prepared solution of antimony and potassium tartrate or injections of ampules of antimony thioglycollamide." Fuadin N. N. R. (a trivalent compound of antimony and sodium) is considered by Williamson, Anderson, Kimbrough and Dodson (*THE JOURNAL*, May 27, 1933, p. 1671) to be a "safe and rapid specific for granuloma inguinale."

BED ROCKING AND HEAD BANGING IN CHILDREN

To the Editor:—I have observed a boy since he was 6 months old, two and one-half years ago, who is mentally and physically well developed but who started at that time to get on his hands and knees and rock back and forth while in bed. Later he continued with such force that the bed made a great deal of noise. He also bumps his head on the headboard but doesn't seem to be injuring himself. This habit occurs until he is falling asleep. Of course this is annoying to the parents and I suggested to the mother first to change the bed. This didn't help because the child still insisted on rocking despite the change. I later suggested putting the child to sleep on his mattress on the floor in order to prevent excess movement. However, the child was put back into his bed because of the changed thermal condition of the room. He showed a definite improvement, rocking and bumping only occasionally. After the change of the temperature and weather conditions permit, I shall insist on putting the child back on the floor at least for six more months. The mother's second child was delivered by me six months ago, in every respect a normal boy. This child, now 6 months old, has started to get on his knees and hands and rock back and forth also. He seems to enjoy this process too. The mother is seeking my advice on how to prevent this annoying habit developed by her older child. My questions are: Did I advise the mother right regarding the breaking of this habit formed by the older child? What could you suggest to prevent the developing of this habit by the second child?

M.D., Illinois.

ANSWER:—There seems to be no good reason why any effort should be made to break the habit of bed rocking or head banging. Just why these habits develop is not known. It is probable that the infant gets some degree of pleasure from them.

There is no particular method that can be suggested for the prevention of the development to this type of habit. It is probably more liable to develop in so-called nervous infants than in more phlegmatic children. Ignoring the habits completely usually causes their disappearance.

It probably is not advisable to have the child sleep on a mattress on the floor. The movement in the bed will do no harm. The bed may be fixed so that it will not shake. This will prevent noise and may serve somewhat in helping to overcome the habit.

AMENORRHEA

To the Editor:—A well developed girl of 20 years, weighing 120 pounds (54 Kg.), began to menstruate at 14. The periods were regular for a time, then missed a month or more at a time, and finally stopped three years ago without any symptoms. Treatment has been administered since June at weekly intervals, consisting of twelve injections of arginin with tablets by mouth, five injections of 1 cc. each of antuitrin, about thirty-six capsules of theelin and about forty thyroid tablets. There has been no response thus far. The breasts are well developed. There is an ordinary amount of pubic hair. The vaginal tract seems fairly well developed. The vagina is somewhat small, the uterus not infantile.

J. W. Mambert, M. D., Hudson, N. Y.

ANSWER:—There is rarely any need to treat secondary amenorrhea unless a woman has tried and has failed to have children. In such a case it is generally assumed that the amenorrhea is an indication of the absence of ovulation. However, it does happen occasionally that some women who do not menstruate and have an intact uterus do ovulate in spite of the absence of uterine bleeding. The way to determine the presence or absence of ovulation in cases of amenorrhea is to perform an endometrial biopsy once every two weeks. If microscopic study of the tissue obtained reveals a secretory endometrium, this is evidence of ovulation. A woman may ovulate at certain times and not at others. If three or four successive endometrial biopsies fail to reveal a secretory endometrium, ovulation is absent. In such cases one may try to stimulate ovulation by means of equine gonadotropic therapy.

This patient should have one or more basal metabolism studies made. If the rate is low, thyroid therapy should be instituted. Thyroid extract alone in proper doses may bring about a return of the menses. If the basal metabolic rate is normal and the patient's general health is good, she should be told that there is no need to restore her monthly periods at the present time. If, however, she insists, the simplest type of therapy is to give 50,000 international units of estrogen

hypodermically twice a week for three weeks. Generally after this medication bleeding sets in. Nearly always, to produce further bleeding, more hypodermic doses of estrogen must be given.

RECURRENCE IN PITYRIASIS ROSEA

To the Editor:—A patient with pityriasis rosea states that the same condition was diagnosed eight years ago. How often does pityriasis rosea occur more than once in the same individual, and could you give me a few references to the literature on this subject?

J. T. Marr, M.D., Sterling, Kan.

ANSWER:—The clinical picture in pityriasis rosea is typical and is vividly described in the standard textbooks on dermatology. Until recently the feeling among dermatologists was that recurrence of the disease is rare, but occasionally dermatologists have seen bona fide cases of this condition a second time in individuals whom they have previously treated for pityriasis rosea. For references see Rulison, R. H.: Pityriasis Rosea: A Few Simple Facts, *Arch. Dermat. & Syph.* 7:163 (Feb.) 1923. Ormsby, O. S.: A Practical Treatise on Diseases of the Skin, ed. 4, Philadelphia, Lea & Febiger, 1934, page 285, quotes von Szabóky: Beiträge zur Aetiologie der Pityriasis rosae, *Monatsh. f. prakt. Dermat.* 42:495, 1906, as stating, among other things, that in 50 per cent of 119 cases of this disease there was a return of symptoms in only one. A recent article on pityriasis rosea is that by Niles, H. D., and Klumpp, Margaret M.: Pityriasis Rosea: Review of the Literature and Report of 219 Cases, in Thirty-Eight of Which Convalescent Serum Was Used, *Arch. Dermat. & Syph.* 41:265 (Feb.) 1940.

POISON IVY

To the Editor:—Many years ago I was affected with poison ivy on both hands which spread rapidly up my arms in the usual way. After little relief from the usual methods of treatment, I covered both arms to the elbows with collodion. Relief was instantaneous and in due time the inflammation stopped. I have advised this treatment often to others, always with complete success, consisting of quick relief, stoppage of spreading and rapid cure. Most other methods advised require that the patient stop work if the method is to be effective.

Samuel B. Woodward, M.D., Worcester, Mass.

HEREDITARY FACTOR IN FACIAL PALSY

To the Editor:—In *Queries and Minor Notes* Dec. 16, 1939, page 2260, there was an inquiry from a New York physician who reported attacks of peripheral facial paralysis in a patient, the patient's father and his older brother. The question was whether there is a form of familial peripheral facial paralysis. The answer was "No hereditary factor in facial paralysis. . . . The disorder is so common that it might easily happen to affect several members of a family." Two facts do speak in favor of the assumption that there might be a constitutional hereditary component in the usual peripheral facial palsy: It occurs in members of the same family and it recurs in the same patient. Charcot first reported cases of facial palsy occurring in families. Neumann reported facial palsy in three sisters together with the child and grandchild of one of them. In addition he collected forty-one similar observations. Despaigne reported twenty cases and reports of further cases were published by Rauzier, Rossie, Sarbó, Auerbach, Weber, Simmonds, Oppenheim, Frey, Moebius, Bernhardt, Hoffmann, Hatschek, Huebschmann, Donath, Lannois, Mendel and Arkwright. Some of these authors stressed that in the hereditary cases the palsy resulted from trivial causes. The apparent presence of some constitutional factor in facial palsy is further evidenced by its recurrence in the same patient. Mouriquand and his co-workers reported the case of a girl who had eight attacks of facial palsy in two years. Remark found recurrence in 3 per cent of the cases, Bernhardt in 7.2, Sossinka in 3, Fuchs in 5.7, Peters in 6, Waterman in 2.7, Merwirth in 7.7 and Petit in 6. Of special interest in the problem of a hereditary factor in facial palsy are those cases in which palsy occurred and recurred in members of the same family. Such cases were reported by Rosenthal and by Johnson and Stoesser. In contradistinction to Erb, most of the authors (Charcot, Oppenheim, Eulenburg, Neumann, Alexander, Wexberg, Mendel, Huebschmann, Hoffmann, Urbantschitsch and others) assumed that some hereditary constitutional predisposition may be responsible for the occurrence of facial palsy. Nothing definite is known about the nature of this predisposition. Sarbó, Wassermann, Marfan and Delille, Despaigne, Phylip, Jendrassik, Higier, Kelly and Moskowitz assumed that an inherited anomaly or a narrowing of the fallopian canal were responsible. Others spoke of a hereditary vulnerability of the nerves that makes them susceptible to otherwise harmless noxae. Julius Bauer stated that there are "neuropathic-arthritic constitutional anomalies" in families with facial palsy. Kinnier Wilson pertinently summarized the problem in saying "To be compelled to resort to some form of 'predisposition' (anatomical or otherwise) is unsatisfactory but perhaps inevitable."

In this connection it is of interest to note that in other forms of mononeuritis, e.g., of the radial nerve (Mendel), of ramus superficialis of the radial nerve (Wartenberg), of nervus cutaneus femoris lateralis (Goldstein, Buchowsky) and even in crutch palsy (Wexberg) a constitutional inherited component has been assumed. It was Oppenheim who maintained that some individuals have an inherited tendency to acquire neuritis. Foerster agreed with Oppenheim in assuming that even for the occurrence of a neuritis after local trauma there must be some endogenous disposition.

Robert Wartenberg, M.D., San Francisco.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, June 22, page 2495.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II, Sept. 11-13. Part III, June or July, to be given in medical centers having five or more candidates desiring to take the examination. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: December 1940. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written*. October 21. Applications must be on file not later than September 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: Chicago, Oct. 18-19. Sec., Dr. R. Glen Spurling, 404 Brown Bldg., Louisville, Ky.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral*. Cleveland, Oct. 5. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Oral and written*. New Orleans, January 1941. Final date for filing application is November 15. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF PEDIATRICS: Memphis, Tenn., Nov. 17, preceding the annual meeting of the American Academy of Pediatrics. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF SURGERY: *Written*. Part I. Various centers, October 21. Final date for filing application is September 15. Sec., Dr. J. Stewart Rodman, 225 S. Fifteenth St., Philadelphia.

AMERICAN BOARD OF UROLOGY: *Oral and Written*. Chicago, February 1941. Applications must be on file not later than Oct. 15. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Connecticut March Report

Dr. T. P. Murdock, secretary, Connecticut Medical Examining Board, reports the written examination held at Hartford, March 12-13, 1940. The examination covered nine subjects and included seventy questions. An average of 75 per cent was required to pass. Thirty candidates were examined, seventeen of whom passed and thirteen failed. The following schools were represented:

Connecticut March Homeopathic Examination

Dr. Joseph H. Evans, secretary, Connecticut Homeopathic Medical Examining Board, reports the written examination held at Derby, March 12-13, 1940. The examination covered seven subjects and included seventy questions. An average of 75 per cent was required to pass. One candidate was examined and passed. The following school was represented:

School	PASSED	Year Grad.	Number Passed
Hahnemann Med. College and Hospital of Philadelphia (1939)			1

Book Notices

Obstetrics and Gynecology. By the Departmental Staff of the University of Chicago and Other Contributors. Edited by Fred L. Adair, M.A., M.D., F.A.C.S., Mary Campau Ryerson Professor and Chairman of the Department of Obstetrics and Gynecology, in the University of Chicago, Chicago. Volumes I and II. Cloth. Price, \$20 per set. Pp. 1,000, with 373 illustrations; 1,031, with 314 illustrations. Philadelphia: Lea & Febiger, 1940.

The two volumes prepared by Dr. Adair and the other members of the department of obstetrics and gynecology at the University of Chicago are the culmination of an enormous task. The editor states that this book "is not intended to be a work of reference but it is primarily designed for the medical student and the practitioner of obstetrics and gynecology." The inclusion of a large amount of historical data, numerous charts and tables and a huge amount of statistical information indicates that this book does serve as a reference book as well as a textbook. In chapter x, which contains thirty-three pages, there are twenty-four statistical tables and ten statistical charts. In addition to brief historical introductions in many chapters there is a history of maternal care which occupies twenty-three pages and a history and development of gynecology which takes up nine pages.

The allotment of space to the various subjects is uneven. Little space is devoted to common obstetric and gynecologic operations with which medical students and certainly practitioners should be familiar, but seven chapters with a total of 140 pages are devoted to the newborn in addition to the twenty pages given over to the chapter of intra-uterine growth. In spite of the editor's attempt to avoid repetition and lack of coordination, a number of obstetric and gynecologic subjects are discussed at length in more than one part of the same volume or in both volumes. Thus the subject of menstruation is taken up on pages 240-244 and on pages 491-494 in the same volume. The same neoplastic diseases are discussed extensively in the two volumes. The subject of postpartum hemorrhage is taken up separately from the disorders of the third stage of labor.

Likewise the distribution of the illustrations is unbalanced and occasionally confusing. A large number of illustrations are devoted to unimportant material and, on the other hand, none could be found for certain important subjects in obstetrics and gynecology. Thus, in addition to the large number of figures devoted to statistical charts throughout both volumes there are twenty-five illustrations for the subject of roentgenology in obstetrics and gynecology, seven for tuberculosis of the genitalia (but only one for gonorrhea of the genitalia), nine for the LeFort operation, seventeen showing only the external genitalia, sixteen depicting the breasts, an enormous number of monsters and 107 illustrations in the chapter on the relationship of pediatrics to obstetrics (140 pages). On the other hand, there are no illustrations showing internal version (there are four for external version), no illustrations showing packing of the uterus for postpartum hemorrhage, none on how to make an abdominal diagnosis in labor by means of the four "grips," none on how to take the external pelvic measurements or how to estimate and measure the pelvic outlet, none on how vaginal pessaries are to be used or even what such pessaries look like, none on the Rubin insufflation test and none on how to perform

a simple curettage, an abdominal hysterectomy or a vaginal hysterectomy. A few illustrations are duplicated in the two volumes (figures 329 and 330 in volume I are the same as figures 71 and 72 in volume II). Two of the three illustrations on hydatid mole are in the chapter on abortion in volume I and the third illustration is in the chapter on neoplastic diseases of the female genitalia in volume II.

There is an occasional error. In volume II (p. 868) is a list of mortality rates for the hysterectomies performed at the Chicago Lying-in Hospital. These are listed as follows: 167 complete abdominal hysterectomies with a death rate of 0.12 per cent, 416 incomplete abdominal hysterectomies, 0.002 per cent, and 180 vaginal hysterectomies, 0.11 per cent. The word "position" is used interchangeably with the word "presentation." The authors speak of "face position."

There is an extensive appendix which contains valuable information concerning dietetics, laboratory methods, vital statistics and comparison of weights, measures and temperatures. Likewise there is a long list of references occupying twenty-five pages. The index, which occupies thirty-six pages, is reprinted in both volumes, undoubtedly for convenience. The volumes are large.

An enormous amount of time and effort have been put into this elaborate work. It is well written in a style easy to read. The subjects of obstetrics and gynecology are fully covered, although not evenly distributed or illustrated. As shown in the list of contributors an appreciable proportion of both volumes was presumably written by young men and women who were instructors, residents and even interns at the Chicago Lying-in Hospital. Therefore many of the ideas expressed and much of the advice given by these contributors in the chapters they wrote are recommendations made by obstetric and gynecologic authorities consulted by these young obstetricians and not the fruits of their own experience, which of necessity must have been limited. The illustrations are most instructive. The drawings are well done and excellently reproduced and the typography is clear. Dr. Adair and his associates are to be complimented on their accomplishment.

Nutrition and Physical Degeneration: A Comparison of Primitive and Modern Diets and Their Effects. By Weston A. Price, M.S., D.D.S., F.A.C.D. Foreword by Earnest Albert Hooton, Professor of Anthropology, Harvard University, Boston. Cloth. Price, \$5. Pp. 431, with 134 illustrations. New York & London: Paul B. Hoeber, Inc., 1939.

The author's major interest is oral degeneration and oral disease. His approach to the problem is evangelistic rather than scientific. He is first appalled by "the progressive decline of modern civilization" because of the "physical, mental and moral deterioration of the modernized peoples." In the second place he is amazed and inspired by the revelation of the fund of wisdom, especially nutritional, in the culture and customs of primitive people and by their physical fitness. And in the third place he proposes as the remedy for this progressive decline that "We too, like the successful primitive stocks, can make, as a first requisite, provision for adequate nutrition for generation and growth," and second, for the regulation of overloads such as pregnancy. His dietary program for the control of dental caries differs but little from that recommended by other more conventional nutritionists, namely one rich in vitamins, in minerals, in fresh fruits and in fresh vegetables and one low in highly refined cereals and cereal products. It is composed of "a menu that is low in starches and sugars, together with the use of bread and cereal grains freshly ground to retain the full content of the embryo or germ, with milk for growing children and for many adults, and the liberal use of sea foods and organs of animals." To this he recommends the addition of a mixture of equal amounts of a very high vitamin butter and a very high vitamin cod liver oil. There is little reason to accept the verdict of the writer of the foreword that this is an "epochal piece of research." Above all it is the story of an observant, but not wholly unbiased, traveler who relates entertainingly what he discovered during vacation trips to primitive peoples in Switzerland, the Hebrides, North America, Melanesia, Polynesia, Africa and South America. Purposely detailed scientific data are not included although there is considerable information concerning native trade and customs. Both lay and professional readers will no doubt enjoy it whether or not they agree with any or all of the author's conclusions.

Anesthesia: Narcosis, Local, Regional, Spinal. By A. M. Dogliotti, M.D., Professor of Surgery, University of Modena, Modena, Italy. Authorized English translation by Carlo S. Scuderi, M.S., M.D., F.A.C.S., Associate in Surgery, University of Illinois College of Medicine, Chicago, Illinois. Cloth. Price, \$7.50. Pp. 680, with 236 illustrations. Chicago: S. B. Debour, Publishers, 1939.

This is the first Italian treatise on anesthesia. The author seems to have devoted a great deal of his attention to the study of anesthesia and has written a good book. It is essentially a glorified outline. It describes not only points in anesthesia but also technical steps in surgery, so that the book should appeal to both surgeon and anesthetist, but more particularly to the surgeon who supervises anesthesia for his own patients. Dogliotti has limited himself largely to a practical discussion. The book is freely illustrated and is one that will be of value to all specialists in anesthesia and should be an excellent reference book for any library that wishes to obtain a book which covers all phases of anesthesia.

Choice and Change of Doctors: A Study of the Consumer of Medical Services Conducted Under the Auspices of the Committee on Research in Medical Economics. By Gladys V. Swackhamer. Paper. Pp. 47. New York: The Committee, 1939.

From interviews of 365 households with "a high proportion of foreign born and first generation Americans" living in the slums and crowded tenement districts of the largest city in this hemisphere, it was discovered that the choices of medical service were extremely varied and not usually very wise. While one third, even of these families, tended to have a family doctor, they were frequently led to try other sources of medical care. The medical profession has known these facts for a long time and, as in so many other fields of medical activity for the defects in which the profession is criticized, has been about the only body that has tried to improve this condition. Several county medical societies have set up plans to give systematic guidance in the selection of physicians, and the profession has long been studying means of educating the public in methods of more intelligent choice. It is noteworthy that the study does not show any superiority of medical care under such systems of prepayment as existed and that, in a remarkably high percentage of the instances given, the exercise of a new choice seems to have improved the medical service received. No reference is made to the fact that it is the existence of a potential choice that is one of the most important means of protection against the worst types of medical service. No effort is made to show that selection by parties more interested in financial, political or other considerations than standards of medical service would improve the condition. The investigator might have learned much from a study of the history of the compensation clinics in New York City, where injured workers were denied freedom of choice and where, as a result, it required official investigation and legislative action to remove almost incredible abuses.

Medical Uses of Radium: Summary of Reports from Research Centres for 1938. Medical Research Council, Special Report Series, No. 236. Paper. Price, 30 cents; 1s. Pp. 49, with 5 illustrations. London: His Majesty's Stationery Office, 1939.

The Medical Research Council's seventeenth annual report summarizes the medical uses of radium and radon at various research centers in England for the year 1938. The report provides an opportunity for cursory review of the investigations in experimental and clinical fields together with a rapid appraisal of the progress and results of the research. The clinical sections outline the technical methods in use at the various centers for treatment of cancer and include a number of the tables containing pertinent statistical data. A special section on telerradium therapy reports the progress and investigations of the use of the radium beam. Of particular interest is the use of large radium sources (10 Gm.) and parallel investigations of 200 kilovolt x-ray and 5 Gm. radium units.

Heil Hunger! Health Under Hitler. By Dr. Martin Gumpert. Translated from the German by Maurice Samuel. Cloth. Price, \$1.75. Pp. 128. New York & Toronto: Alliance Book Corporation; Longmans, Green & Company, 1940.

From material "all of it provided by Nazi authorities and Hitler officials, by the doctors, statisticians and scientists of the Third Reich," a terrible picture is painted of health conditions in Germany. Rickets is on the increase. A systematic examination of the school children of Munich "discovered that only 3.5 per cent were free from symptoms of rickets!" As the

result of undernourishment and excessive athleticism, German youths are already invalids. The annual suicide rate is 4.1 per 10,000 compared with 1.4 in the United States. Tuberculosis, after long years of decline, is once more on the increase, and the tuberculous are now compelled to undergo heavy work in order to speed up production and this is also being defended with pseudoscientific arguments. The records of the sickness insurance system show an increase in cases of sickness of 20.3 per cent between 1933 and 1936. In spite of the claims of the Nazi régime that women were to be returned to the home, twice as many women were employed for wages in 1938 as in 1929. The destruction of scientific training in the universities and the encouragement of quackery by the government is lowering the quality of medical care. The disabilities reported among those called up for military service are steadily increasing. Practically all these statements are documented from official sources available in this country.

Aids to Dermatology and Venereal Disease. By Robert M. B. MacKenna, M.A., M.D., B.Ch., Hon. Dermatologist, Royal Liverpool United Hospital (Royal Southern Hospital), Liverpool. Second edition. Cloth. Price, \$1.25. Pp. 284, with 7 illustrations. Baltimore: William Wood & Company, 1939.

This edition, like the first, has been prepared with the hope that students and practitioners might find within its covers a convenient synopsis of the commoner cutaneous and venereal diseases. The book has been thoroughly revised with especial attention to revision of therapeutics, the chapters on tuberculids, dermatitis and prurigo. In the therapy of erysipelas the use of sulfanilamide, among other things, is discussed in a brief but adequate manner. While the work is small and does not contain the photographs seen in larger textbooks, the succinct descriptions of the conditions discussed and various agents used by the dermatologist are essentially good and complete enough to give one a basis for further reading in the larger textbooks or monographs if more information is desired. There are a number of illustrated sketches. The treatment of syphilis is excellent and succinctly discussed and includes a brief discussion of the toxic effects of treatment. On the whole, this work is to be highly recommended for one desiring a synopsis of dermatology for a background to be complemented by further study of the large standard textbooks when desired.

Modern Urology for Nurses. By Sheila Maureen Dwyer, R.N., Supervisor, J. Bentley Squier Urological Clinic, Presbyterian Hospital, New York, and George W. Fish, M.D., Associate Professor of Urology, College of Physicians and Surgeons, Columbia University, New York City. With a foreword by Helen Young, R.N., Director of Nurses and Nursing Service, Columbia-Presbyterian Medical Center in the City of New York. Cloth. Price, \$3.25. Pp. 290, with 60 illustrations. Philadelphia: Lea & Febiger, 1940.

The title aptly describes the contents of this splendid book. Good nursing, preoperatively and postoperatively, is probably never more urgently required than in urologic cases. The collaboration of these authors, who are well experienced in the care of these patients, from the nurse's as well as the surgeon's point of view, answers a long felt need for a sound basic textbook to prepare a nurse for competent urologic nursing. They are to be congratulated on this accomplishment. An adequate understanding of the pathology and physiology of the urogenital tract is an essential for satisfactory urologic nursing. Possessing it, the nurse can cooperate more intelligently with the physician and realize the importance of certain procedures which otherwise might not have any significance to her. The photographs and drawings with the accompanying text enable the nurse to acquire this understanding and simultaneously the knowledge of the principles of the nursing responsibility for these patients. The sequence of the book is well arranged. The chapters on operative procedures and instruments and their care are excellent references for any surgical nurse. This book should be the means of providing more intelligent attention for patients suffering from urologic entities not only because of its fine presentation of the theory and practice of urologic nursing but also for its complete plan for a urologic service. Of course, it is understood that not all hospitals can equip such a unit as described, but at least a workable plan is submitted which can be altered to suit the needs of individual hospitals.

The book is recommended to hospital training schools, where the chapter on suggestions for a teaching program alone should be a valuable adjunct in preparing the curriculum. Nursing supervisors with urologic cases should not be without a copy; in fact, every graduate nurse will find it a profitable investment.

Handbuch der mikroskopischen Anatomie des Menschen. Herausgegeben von Wilhelm v. Möllendorff. Band VI: Blutgefäß- und Lymphgefäßapparat Innersekretorische Drüsen. Teil 2: Innersekretorische Drüsen I: Schilddrüse, Epithelkörperchen, Langerhanssche Inseln. Bearbeitet von Dr. W. Bargmann, Dozent an der Universität Leipzig. Paper. Price, 72 marks. Pp. 306, with 152 illustrations. Berlin: Julius Springer, 1939.

This second part of the sixth volume deals with the thyroid and parathyroid glands and with the islands of Langerhans. It has been prepared by Dr. Bargmann. Since the parathyroids are distinct from the thyroid, both genetically and functionally, Dr. Bargmann does not like to use the name parathyroid. He prefers to call these glands epithelkörperchen, the little epithelial bodies. This section constitutes a thorough review of researches in these fields in all countries up to the time of publication. It includes an exhaustive list of papers published and is indispensable for all research students in the field or for any student who wants to become thoroughly acquainted with the present status of our knowledge in any part of it. The illustrations are taken from these publications or from Dr. Bargmann's own preparations. Many are from colored drawings or photomicrographs. The book presents the general excellence characteristic of the publications of Julius Springer.

A Handbook of Elementary Psychobiology and Psychiatry. By Edward G. Billings, B.S., M.D., Assistant Professor of Psychiatry, University of Colorado School of Medicine, Denver. Cloth. Price, \$2. Pp. 271, with 10 illustrations. New York: Macmillan Company, 1939.

The author is director of the psychiatric liaison department of the Colorado General Hospital. The present book, which is intended to serve as an "orientation manual of psychobiology and psychiatry," is a compendium for students and physicians. It contains the material the author has found the most effective in meeting the needs of students in the study and management of the "disorders of personality functioning as they occur in clinical medicine and psychiatry."

Part I is a brief introduction to psychobiology as developed by Dr. Adolph Meyer, utilizing and defining the terminology coined by Dr. Meyer. Psychobiology is discussed as "the physiology of the total man," as dealing with "the meanings of things in the life of a person." This discussion of personality development and functioning stresses the person as a unit, as an organ for the further integration of functions at the various levels of integration (physicochemical, anatomic, and so on) in the service of the total personality. This highest level of integration, the psychobiologic level, may be studied in terms of aggregates of personal functions (action tendencies, intellectual attributes, emotional-hormonal functions). Charts are included to indicate levels of integration and factors involved in personality development and reaction.

Part II discusses psychiatric examination procedures for adults, for children and for inaccessible patients. Detailed outlines of procedure are provided. The author stresses the importance of proper initial approaches to the patients and of the rapport. The guide for examination of noncooperative patients is that developed by Drs. K. E. Appel and E. A. Strecker.

General psychopathology is discussed in part III. Following a discussion of normal and abnormal personality functioning, the author outlines and describes constitutional psychopathic reactions, the neuroses and the psychoses. Though necessarily condensed, descriptively satisfying accounts of the various commonly encountered clinical entities are offered. A brief chapter on general principles of psychotherapy gives those principles which the author has found to be "conservative, safe, conducive to constant psychopathological research into the genesis and dynamics of the patients' illness and . . . applicable to the rank and file of psychopathological states." Indirect therapeutic procedures, such as palliative measures for relief of symptoms, general supportive and "sublimative" therapies (as occupational therapy), are outlined briefly. Direct therapy is discussed in terms first of management of "dynamic factors in the external milieu" and secondary in management of the personality-determined factors. For personality study, psychoanalysis as a

methodology is merely referred to and a bibliography provided, and the "distributive analysis," the methods of Adolph Meyer, are briefly discussed and outlined.

This handbook is a carefully considered work which, in the main, should be quite useful to medical students. The clinical aspects of the book will be more comprehensible to the medical student than the introductory material. The excellent clinical discussions lack clarity of formulation of dynamics. This reflects half-hearted acceptance of those principles of dynamic psychology the more complete expression of which would be found in the formulations of psychoanalytic psychology. The format of the book is such that it can be slipped into the student's pocket, but this size renders many of the illustrations and tables all but useless on account of the microscopic size of the type.

Précis de médecine des enfants. Par P. Nobécourt, professeur de clinique médicale des enfants à la Faculté de médecine de Paris. Sixth edition. Cloth. Price, 175 francs. Pp. 1303, with 604 illustrations. Paris: Masson & Cie, 1939.

As the title suggests, the work is a summary of clinical pediatrics. It consists of brief clinical descriptions, often illustrated, of almost every condition met by the pediatrician. Little space is given to therapy or to newer scientific developments. Little emphasis is laid on subjects such as the vitamins and deficiency diseases, and the references are infrequent and out of date. For instance, in the discussion of rickets the insignificant emphasis laid on vitamin D is in contrast to the hysterical overemphasis placed on it by our American commercial propaganda. The author gives half a page to deficiencies of amino acids and another half page to the minerals. The book is unlike American textbooks or even our clinical publications. The clinical descriptions are often so much briefer than ours that it is hard to consider them as being an aid to the student. On the other hand the lack of space given to the newer advances in etiology and therapy interferes with its interest to the pediatrician. The clinical descriptions are characteristically French in being clear and to the point. The book may have interest to those who wish a compact reference book to find in a few moments a ready description of almost any condition met in the field of pediatrics.

An Outline of Medical Psychology. By E. Fretson Skinner, M.A., M.D., F.R.C.P., Physician in charge of the Psychological Clinic, Sheffield Royal Hospital, London. Cloth. Price, 6s. Pp. 173. London: H. K. Lewis & Co., Ltd., 1939.

This British volume attempts in a small space to cover the significant background material in psychology and to present a brief picture of a few of the neuroses. It is divided into three parts, the first dealing with physiology but, unfortunately, including discussions of the development of the mind, the unconscious mind and instinct and emotion, which this reviewer scarcely can see could be tied up with physiology as the author presents it. The more recent developments in psychobiology and psychosomatic medicine do present a relationship of mind to the central nervous system but that is not the presentation which Skinner develops in his book. The second part treats of psychopathology and this part is a very brief summary of freudian psychoanalysis stressing dreams, the unconscious and sexuality. The third part is devoted to the clinical aspect of the subject, including a discussion of about ten pages on hysteria but on no other psychoneurosis, although a chapter is devoted to the brief presentation of about nine cases of assorted psychoneuroses. There is a brief discussion of therapy. Skinner claims that the book is intended for the medical student who wishes a brief introduction. Surely there are many books which have been published prior to this one which could be more adequate to such a purpose. The genesis of the psychoses, modern psychology, psychodynamics, psychobiology and diagnosis and treatment of the psychoses are all omitted. Relationship of the mental case to society is barely touched on and the discussions of therapy are so brief as to give rather an invalid impression than a valid one. This book cannot replace the more conventional manuals of psychiatry, and it is to be hoped that the medical student is not in such a condition as to require a simpler volume than the textbooks prepared in this country by Rosanoff, Noyes or others by the time he reaches the place in the medical curriculum where he needs instruction in medical psychology.

Sketches in Psychosomatic Medicine. By Smith Ely Jelliffe, M.D., Consulting Neurologist to Manhattan State and Kings Park Hospitals, New York. Nervous and Mental Disease Monographs, No. 65. Boards. Price, \$3. Pp. 155, with illustrations. New York: Nervous and Mental Disease Monographs, 1939.

This collection of papers written by Dr. Jelliffe over a period of years is especially interesting at this time because of the intensified interest in psychosomatic problems. The author has long been the most prominent advocate of principles of psychosomatic medicine. In his textbook, written with the late Dr. White, he has always attempted to integrate psychologic factors with problems of organic medicine. In the collected papers within this volume the catholic interest of the author is indicated by the range of subjects about which he has written. From myopia to contractures of the hand one finds evidences of unconscious psychologic factors in the etiology. Dr. Jelliffe's work will long remain as a milestone in the development of psychosomatic medicine and his original investigations are of great interest. However, the actual correlations between emotional disturbances and physical dysfunctions are not worked out in the detail that we now have at our command. The field of psychoanalysis has progressed to such an extent in the last two decades that much of the psychologic material in this series of collected papers has been amplified and improved on to a great extent. The work then has a value as a historical brochure and as indicating certain basic principles.

The Genetics of Schizophrenia: A Study of Heredity and Reproduction in the Families of 1,087 Schizophrenics. By Franz J. Kallmann, M.D., New York State Psychiatric Institute and Hospital, New York. With the assistance of Senta Jonas Rypins, A.B., and with an introduction by Nolan D. C. Lewis, M.D., Director, New York State Psychiatric Institute and Hospital. Cloth. Price, \$5. Pp. 291. New York City: J. J. Augustin Publisher, 1938.

This book presents the results of a study of 1,087 schizophrenic probands and their families. The material, obtained in a German population, by painstaking investigation of schizophrenic patients in the Herzberge Hospital of Berlin between 1893 and 1902, although unselected, was rigorously classified. All blood relations were exhaustively surveyed and discriminately diagnosed. Statistical, classificatory, demographic and social analysis yielded figures for fertility, mortality, disease expectancy and genetic data.

The author, in his foreword, states that the principal aim of the investigations was to offer conclusive proof of the inheritance of schizophrenia and to establish a dependable basis for the clinical and eugenic activities of psychiatry. Analysis of the data reveals hereditoconstitutional factors having a decisive influence in the origin of schizophrenia, as the following conclusions indicate:

1. Families affected by schizophrenia show a progressive and uninterrupted social decline.
2. Germinally affected and overt schizophrenic individuals show a lowered marriage and birth rate, although not sufficient to lead to self elimination. Catatonic hebephrenic patients fall below the general population by one half in this regard.
3. The probable recurrence of schizophrenia is nineteen times greater in children of the schizophrenic than it is in the general population.
4. Predisposition to schizophrenia is specific, but phenotypic manifestations vary, depending on the interplay of somatic and constitutional factors.
5. Frequency-expectancy of schizophrenia in children does not depend on the sex of the schizophrenic parent or on whether they were born before or after disease onset.
6. Psychopathologic abnormalities, epilepsy, feeble-mindedness, neurosyphilis, alcoholism and criminality bear no biologic or hereditary relationship to the hereditary circle of schizophrenia. Each follows its own pattern of heredity and has independent selective factors. The blood kin of schizophrenic probands show no increase in expectancy of any of the abnormalities except as far as increased alcoholism and criminality is conditioned by the more frequent manifestation of the schizophrenic psychosis.
7. There is a consistent association of frequency of schizophrenia with mortality from tuberculosis, which may have com-

mon origin in a hereditary functional deficiency of the reticulo-endothelial system. The correlation and concordance are such that expectancy of schizophrenia and mortality from tuberculosis are the same in all blood relations of schizophrenic probands and lead to the assumption that the two tendencies are gene coupled and take the same recessive hereditary course.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Disability Resulting from Repeated Bruising Not an Occupational Disease.—

In the course of her employment, the plaintiff operated for about two weeks a machine for sewing cuffs on shirts. To operate the machine it was necessary that she exert lateral pressure with her right knee against the flat side of an elliptical plate, which was attached by a set screw to a rod extending to the so-called table of the machine. She was called on to exert this lateral pressure with her right knee about 288 times an hour. The mechanism on the machine used by the plaintiff was defective. At times the set screw would become loose and the plate would slide around the rod so that its edge, or the screw itself, instead of the flat surface of the plate, would be pressed by the operator's knee. The plaintiff's knee gradually became sore. On one occasion, according to the testimony of the plaintiff, the "screw part" hit her knee and bruised it badly. It became acutely inflamed and she was forced to cease working. For the resulting disability she sought compensation under the workmen's compensation act of Maryland and the matter eventually reached the Court of Appeals of Maryland.

The employer contended that the plaintiff's disability resulted from an occupational disease and not from an accidental injury and was not, therefore, compensable under the Maryland act. In the opinion of the Court of Appeals, the disability in question did not result from an occupational disease since the very nature of the injury did not satisfy the "literary definition" of a disease, which ordinarily implies some morbid derangement of bodily functions. The injury suffered here, said the court, was more consistent with the injury and destruction of tissue by the application of external force, such as a blow. The term "accidental injury" is generally accepted as meaning physical injury to the bodily tissues caused by some unusual condition or occurrence in the employment and is associated in varying degrees with the elements of force, violence and surprise. While the word "accident" connotes suddenness, it does not necessarily imply that the occurrence is instantaneous. An injury may be accidental even though the conditions which caused it extended over a considerable period of time.

In the instant case, continued the court, there was evidence legally sufficient to support the conclusion of the trial court, which overruled the holding of the accident commission, that the plaintiff's knee was bruised and injured by the operation of the knee press, which because of faulty adjustment was stiff and hard to move; that while she knew of the faulty adjustment she did not know and did not expect that operating the knee press would injure her knee, and, finally, that the injury which caused the acute inflammation which prevented her from continuing to operate the knee press was caused by the press plate slipping around the rod to which it was fastened so that when she pressed her knee against it she struck the set screw instead of the smooth surface of the plate. These facts, in the opinion of the court, were sufficient to require the submission to the jury of the issue of whether the plaintiff's disability resulted from an accidental injury arising out of and in the course of her employment.

Accordingly, the Court of Appeals affirmed the judgment of the trial court and ordered, in effect, that compensation be awarded the plaintiff.—*Foble v. Knafely* (Md.), 6 A. (2d) 48.

Charitable Hospitals: Liability for Burns to Child of Pay Patient.—A pay patient, Mrs. Miller, was delivered of a male child at St. Joseph's Hospital in Tacoma, Wash., one of eight hospitals owned and operated by the defendant corporation, the Sisters of St. Frances. On the ninth evening after the child's birth he was entrusted to the sole charge of a student nurse employed by the hospital. She placed him on his back about one foot from the edge of an adult's bed located about one inch from a heated radiator. She then left the room for a few minutes at the request of her supervisor, and on her return she found the baby lying on his back with his head resting against the radiator. The child sustained severe burns on his head which left permanent scars and a defect in the top of his skull. Subsequently the mother and father of the child brought suit against the defendants, the corporation and the student nurse, to recover damages for the injuries which the child had sustained. From a judgment in favor of the plaintiff the defendants appealed to the Supreme Court of Washington.

The Supreme Court agreed with the defendants' contention that the Sisters of St. Frances is a charitable organization and is not liable for the alleged negligent acts of its servant. In this state, said the court, a charitable hospital conducted not for profit is not liable under the rule of respondent superior for the negligence of its employees unless it was negligent in failing to exercise ordinary care in their selection and retention. Also, the fact that patrons of a hospital pay for services rendered does not deprive the institution of its status as a charitable organization, provided that its income is devoted to the establishment of its charitable purposes and no portion thereof is diverted to private profit or advantage. In the judgment of the court, the articles of incorporation and by-laws of the defendant corporation showed that it was organized as a charitable corporation, and there was no evidence that any of the corporation's officers or agents diverted to the private advantage or profit of any person any of the income derived from the operation of the hospital.

Although the trial court correctly instructed the jury that the defendant corporation was a charitable institution, it erred, said the Supreme Court, when it admitted over the defendants' objection evidence introduced by the plaintiff showing the amount of property owned by the corporation, the amount of cash St. Joseph's Hospital had on hand and the name of the bank in which it was deposited, and the excess of the hospital's income over disbursements and the use of such excess to reduce a mortgage on the hospital property. The mere fact that the income of a corporation exceeds its operating expenses does not make it any less a charitable organization if the excess of income over expenditures is used for carrying on the charitable purposes for which it was organized. The payment of a legitimate corporate indebtedness, such as a mortgage, is certainly in furtherance of the charitable purposes of a corporation. In the opinion of the court, the admission of the evidence objected to by the defendants was improper because such evidence had no bearing whatever on any issue in the case. It was not preliminary to nor in support of any evidence that any profit or personal gain from the operation of the hospital accrued to any trustee, stockholder or individual.

Accordingly, the judgment of the trial court in favor of the plaintiff was reversed and the case remanded for a new trial.—*Miller et al. v. Mohr et al.; Same v. Sisters of St. Frances et al.* (Wash.), 89 P. (2d) 807.

COMING MEETINGS

National Medical Association, Houston, Tex., Aug. 12-16. Dr. John T. Givens, 1108 Church St., Norfolk, Va., General Secretary.
Pacific Northwest Medical Association, Spokane, Wash., July 10-13. Dr. C. W. Countryman, 407 Riverside Ave., Spokane, Wash., Secretary.
Washington State Medical Association, Tacoma, Aug. 26-28. Dr. V. W. Spickard, 1305 Fourth Ave., Seattle, Secretary.
West Virginia State Medical Association, White Sulphur Springs, July 29-31. Mr. Joe W. Savage, Public Library Bldg., Charleston, Executive Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Appendical Oxyuriasis. E. I. Greene and J. M. Greene, Chicago.—p. 440.

Active Immunization Against Tetanus.—Gold used a purified, concentrated tetanus toxoid (tetanus toxoid topagen) intranasally for active immunization of 145 human beings. With the patient prone on the table, the head hyperextended, 0.1 cc. (two or three drops) of topagen was introduced into each nostril. The 145 subjects were divided into eight groups: Group A received tetanus toxoid topagen exclusively for the primary course of treatment; groups B, C and D received one subcutaneous injection of alum precipitated tetanus toxoid and two or three daily intranasal instillations of tetanus toxoid topagen; prior to nasal treatment groups E, F, G and H were injected with two or more doses of alum-precipitated toxoid or three or more doses of plain toxoid or plain toxoid with 0.4 per cent alum. The antitoxin titer was determined before the first instillation of tetanus toxoid topagen and thereafter at frequent inter-

vals. The results obtained in groups A, B and C reveal the importance of subcutaneous injection of alum toxoid. It cannot be replaced by three daily intranasal instillations of tetanus toxoid topagen. To render the antitoxin-producing cells of the body capable of responding to intranasally administered toxoid, it is necessary to introduce within the host a definite amount of toxoid. This did not take place in group A. A greater number of subjects reached the 0.1 unit level of antitoxin earlier in group C, in which three daily instillations were given, than in group B, in which there were two daily instillations. Of twenty-four subjects tested seven days after the second injection of alum toxoid, six showed a level of less than 0.1 unit, while the rest had levels of 0.1 unit or more of antitoxin per cubic centimeter of blood serum. Forty-five subjects tested one month after the second injection of toxoid showed more than 0.1 unit of antitoxin. The protection produced by intranasal topagen develops less promptly and is not as lasting as that which follows the injection of a second dose of tetanus alum precipitated toxoid. A substantial immunity developed in the eighty-seven subjects as the result of the previous injection of two or more doses of tetanus toxoid. One week after the first instillation of topagen ten members of group G who had received only one nasal application showed an increase in titer above that of the control test, while fourteen showed no increase over the control values or still had a level of less than 0.1 unit of antitoxin. Eighteen group E subjects who were given two nasal instillations on successive days showed an increase over the control titer, while seven showed only control values. Of the subjects in group E who had received three nasal applications on successive days, twenty-two showed an increase over the control values while four showed either no increase or levels of less than 0.1 unit. In groups E and F (receiving three daily nasal instillations as a "repeat" dose), about the same number of persons showed a further increase in titer between the seventh and the ninth day after the first instillation of tetanus toxoid topagen. In group G, following the administration of the second intranasal dose, there was a definite increase in titer two days later. At the end of two weeks, there was no great difference between the three groups. Nasal instillations of tetanus toxoid topagen on three successive days produce a more rapid rise in antitoxin titer than do two daily or two weekly instillations. Group H subjects who received three weekly nasal applications of toxoid did not show better immediate results than did group G. At the end of three months the patients had an antitoxin titer well above the control value, and twenty-three members of groups E, F and H showed good protection when tested six months after the "repeat" instillation. Therefore, to produce and maintain immunity, it is necessary first to render the subject capable of responding to intranasal instillations of tetanus toxoid topagen by two primary doses of tetanus alum precipitated toxoid given ninety days apart and second to repeat the course of nasal instillations every six months.

The Retinal Vessels and Heart Size in Hypertension.—Roesler and his associates selected eighty patients with uncomplicated cases of essential hypertension; forty-two were females and thirty-eight were males between the ages of 12½ and 73 years. The patients had a diastolic blood pressure of at least 95 and a systolic of at least 150 mm. of mercury. Examination of the fundus revealed retinal arteriolar changes of the hypertensive type in all cases; seventy-one were classified as having advanced to the stage of sclerosis while the remainder

were in the preorganic stage of the disease. Electrocardiographic study showed final deflection changes in fifty-five. Left axis deviation occurred in sixty-two. Final deflection changes were associated with left axis deviation in forty-six cases, while left axis deviation occurred without associated final deflection changes in sixteen. In nine instances the electrocardiogram was normal. Of the electrocardiograms 31.3 per cent revealed no significant changes. The orthodiagraphic study of fifty-nine patients showed absence of cardiac enlargement in thirteen, a slight to moderate enlargement in thirty and marked enlargement in sixteen. There is a trend toward a positive correlation between electrocardiographic alterations, cardiac enlargement and the grade of the retinal arteriolar changes, and between electrocardiographic alterations and the degree of cardiac enlargement. This correlation was not demonstrated to be of high statistical significance. The irregular distribution of the vascular processes and the lack of parallelism between the systemic and the central retinal artery blood pressures may account for a part of this lack of correlation. As there is an inadequate correlation between the three criteria in question, it seems desirable to have an evaluation of the eyeground, the electrocardiogram and the heart size in addition to the more routine studies when a prognosis for essential hypertension is attempted.

Vitamin Therapy in Dermatology.—Maynard observed for three months two groups of seventy and sixty patients respectively with acne treated with vitamin D. In the first group 75.6 and in the second 83.4 per cent showed satisfactory results; that is, thirty-two patients of each group were healed at three months. A similar study of twenty-seven patients with acne treated with carotene gave 50 per cent satisfactory results. In the first series an average dose of from 20 to 30 drops (10,000 to 15,000 U. S. P. units) of a vitamin D preparation (viosterol in oil) was given daily. Since then 30 drops (10,000 U. S. P. units) of a synthetic crystalline vitamin D₂ product (calciferol) has been given each morning for three weeks and then 20 drops twice daily (12,500 U. S. P. units). All doses were taken in milk. Three patients with localized scleroderma were satisfactorily treated with vitamin D alone. Sclerosis following an overdose of roentgen therapy gave a promising response in two cases. One patient with pemphigus in the early stages recovered after taking large doses of vitamin D. She had a relapse when the vitamin was discontinued and recovered when treatment was resumed. A young teacher with acquired leukonychia totalis regained normal nail structure after treatment with vitamin D. The majority of patients with psoriasis did not get worse in the winter on vitamin D doses of from 10,000 to 12,000 units

throughout the season. Heavier doses are probably justifiable in selected cases. The vitamin has been administered to children with atopic flexural eczema with substantial benefit. It cannot be stated that lack of vitamin D or calcium alone is responsible, for acne is not observed in rachitic infants. It also is not a factor in osteoporosis or osteomalacia, although these diseases are associated with vitamin D and calcium deficiencies. Acne is a disease occurring in the period of sexual and glandular activity. It is apparently associated with cyclic sexual activity in males and is possibly made worse by excessive sexual practices. The greatest benefit of using vitamin D in acne, in the author's opinion, has been the avoidance of roentgen therapy, which too often becomes the master rather than the servant of the physician.

Cutaneous Excretion of Sulfanilamide.—Cornbleet determined the partition and storage of sulfanilamide in the blood and skin of dogs and its concentration and persistence in the blood, unfiltered sweat and filtered sweat of human beings. In some cases a sweat bath caused the reappearance of sulfanilamide in the blood several days after the drug had disappeared from it. Sulfanilamide appears in the skin soon after its administration. The quantity deposited there accounts for a large share of the entire amount present in the body. Sulfanilamide may be of value, therefore, in certain kinds of infections within the skin. Through the medium of sweat, sulfanilamide is rapidly made available at the surface of the skin. There is some clinical evidence, and more may be expected in the future, to show that sulfanilamide is of benefit for the "streptococci," or superficial streptococcal infections of the skin and its folds. Untoward reactions occur with sufficient frequency to withhold its use in the treatment of the simpler cutaneous infections that respond to less dangerous applications and drugs.

Riboflavin for Rosacea Keratitis and Corneal Vascularization.—In treating thirty-six patients with rosacea keratitis Johnson and Eckardt added from 3 to 4.5 mg. of riboflavin to the diet. Nine of these patients had some cutaneous rosacea of the face. The corneal lesions of thirty-two healed promptly, with no recurrences during riboflavin therapy. Four patients responded slowly or not at all and failed to remain free from symptoms. Of the nine with concomitant cutaneous rosacea four showed satisfactory cutaneous improvement. The five who were not improved had achlorhydria, as demonstrated by the histamine test. The four patients who remain free from cutaneous rosacea cannot be persuaded to have an analysis of their gastric contents. Such an analysis was done for six of the thirty-two patients who remained free from ocular rosacea and normal levels of gastric hydrochloric acid were observed. Only two of the thirty-six patients studied gave a history of having eaten adequate amounts of egg white, liver and milk. These two patients did not improve on the addition of riboflavin to their diet, and an analysis of their gastric contents after the administration of 3 mg. of histamine did not show any free hydro-

chloric acid. Emphasis is placed on the similarity between rosacea keratitis and the ocular condition of rats in which ulcers developed because of dietary riboflavin deficiency. The mechanism is possibly that of inadequate oxidation of enzymes, such as Warburg's yellow enzyme, in the avascular cornea. Rosacea keratitis may be the direct result of riboflavin deficiency. Riboflavin therapy may likewise be of value in certain other forms of corneal vascularization. It apparently is of no value in conditions accompanied by large blood vessels or in which scar tissue is present. Continuous therapy is advisable for constant benefit.

Solid Carbon Dioxide for Vernal Catarrh.—La Rocca used solid carbon dioxide in the treatment of ten patients with vernal catarrh. The catarrh was of the tarsal type in nine cases and of the limbic in one case. The response to the therapy was favorable. It was not wholly successful in two patients, but in these the number of treatments was insufficient. The only patient with the limbic type of catarrh was cured after six treatments. There were no relapses among the cured patients after four years. Solid carbon dioxide has a beneficial effect on the vegetations of vernal catarrh because of its freezing and not because of its chemical properties. In freezing the tissue, the carbon dioxide causes thrombosis of the small vessels of the vegetations, and consequently necrosis of the cells. New connective tissue is formed where the vegetations have been, and whitish shiny scars can be seen in the healed conjunctivas. The failure of other treatments for vernal catarrh (radium, allergic desensitization, vaccines, drugs or transplants of mucous membranes) is probably due to the fact that the pathologic process of vernal catarrh does not lie in the conjunctiva alone but deeper, in the superficial layers of the tarsus.

Testosterone Propionate Percutaneously for Dysmenorrhea.—Abarbanel treated ten patients with dysmenorrhea with or without premenstrual tension by the percutaneous administration of testosterone propionate. The method is indicated when patients object to injections, when they cannot come regularly to the dispensary, in those previously treated by injection with few residual symptoms and in those who, having to leave town, cannot secure the injections. Each patient is urged to receive parenteral therapy first, as the required dosage by this route affords a guide to the amount necessary percutaneously. Patients who do not respond to parenteral therapy usually will not respond to cutaneous administration. The dosage required by the percutaneous route is from three to six times as great as that which is necessary for the subcutaneous route, depending mainly on the vehicle. Sesame oil has proved more effective than any of the ointment bases tried. The areas utilized for percutaneous administration have been the axillary region, the inner part of the thighs or the deltoid region. If the gynecologic

examination is negative, the patient is told to begin percutaneous administration from ten days to two weeks before the expected onset of the next menstruation. If the uterus is small or anatomically misplaced, or both, or if the patient is 30 or more years old, she is advised to begin applications from four or five days after the period is over and to continue them for the remainder of the cycle. The total dosage per cycle has ranged from 20 to 90 mg. of the testosterone. Each patient must be treated individually and no set dosage schedule can be outlined. After three successive periods with little or no discomfort, therapy is discontinued for a month to observe whether improvement is maintained. If not, treatment is repeated. Only one of the author's ten patients was not relieved. The manner in which the dysmenorrhea is relieved will not be clear until it is definitely known what factors initiate the pain. It is reasonable to believe that the relief of the dysmenorrhea may be partly, or even entirely, caused by certain as yet unknown effects of testosterone propionate on the nervous system. Why the relief is permanent in some women is still beyond explanation. The patients treated showed no signs of masculinization. The only possible sign of defeminization was the loss of nymphomaniac tendencies in one patient.

Serum and Sulfapyridine in Pneumococcal Pneumonias.—According to Finland and his collaborators, most workers are agreed that a definition of the conditions under which the use of serum alone, sulfapyridine alone, or the combination of the two, will give the optimum benefit in pneumonia must await the accumulation of a large amount of data subjected to detailed and critical analysis. They present a résumé of the laboratory and clinical studies conducted at the Boston City Hospital during 1938-1939. The laboratory studies suggest that the combination of serum and sulfapyridine represents the optimum therapy in pneumococcal infections. Serum and sulfapyridine for adults with pneumococcal pneumonia are about equally effective when used alone or in combination, while for patients with the worst prognosis the combination of serum and sulfapyridine is more effective than is either agent alone. Instances in which the combined therapy was most effective included patients with bacteremia, particularly those over 50 years of age, those in whom treatment was started late and those with blood cultures yielding moderate or large numbers of pneumococci; patients in whom more than one lobe was involved; most patients over 60 years of age who had more than a mild infection, and patients with pneumonia due to types II, III or possibly V. Since sulfapyridine has a wide range of effectiveness, is simple to administer and is inexpensive, it is advisable to start treatment with it in every case of pneumonia as soon as the clinical diagnosis has been made, but only after blood has been taken for

culture and every effort has been made to obtain sputum for typing. In cases of severe involvement and in pneumonias complicating pregnancy and the puerperium, specific serum should be given as soon as the causative types have been determined or the results of blood cultures have become known. Patients in whom continued drug therapy may prove harmful are best treated with serum as soon as the type is known. They include patients with renal or hepatic disease and those with severe anemias or other blood dyscrasias. The establishment of a balance of antibodies will permit early withdrawal of the drug and thus minimize its ill effects. In all other cases due to specific types of pneumococci, serum should be used if there is no satisfactory response after from twenty-four to thirty-six hours of drug therapy.

Vitamin C Deficiency in Normal Adult.—Crandon and Lund report a case of a normal active adult who placed himself on a vitamin C free diet supplemented by the other known vitamins. No signs or symptoms of scurvy developed over a period of four months, during which the ascorbic acid content of the plasma, white cells and platelets fell to zero. An experimental wound made after twelve weeks of diet, when the plasma readings had been zero for at least forty-four days, showed good healing both grossly and microscopically when a biopsy specimen was taken eleven days later. No lack of intercellular substance could be seen. Analysis of the muscle removed showed no trace of ascorbic acid. Except for the changes in vitamin C concentration, extensive clinical studies revealed only a transient fall in hemoglobin (reversed by iron) and a fall in basal metabolic rate and body weight. While a single case does not permit positive conclusions, the authors suggest that in the absence of multiple avitaminosis, infection or growth factor, a plasma ascorbic acid level of below 0.5 mg. per hundred cubic centimeters is not necessarily dangerously low. Plasma ascorbic acid levels are a poor index of clinical vitamin C deficiency; they probably indicate the degree of saturation, which should not be confused with deficiency. The apparent ascorbic acid content of the circulating white cells and platelets may fall to zero without the appearance of clinical scurvy in an adult on an adequate intake of vitamins other than vitamin C.

- Recent Advances in Study of Pulmonary Diseases. J. L. Wilson, New Orleans.—p. 637.

Hyperpyrexia.—During the last ten years hyperpyrexia has been used in the treatment of about fifty diseases, but it has proved beneficial in only a few. Trautman concludes from 5,500 artificial fever sessions given 985 patients at the Marine Hospital that the air-conditioned cabinet is an effective means of inducing therapeutic hyperpyrexia at fever levels up to 107 F. Only one death occurred among the 985 patients. Hyperpyrexia appears to be a valuable therapeutic adjunct in gonorrhea, syphilis and acute exudative conditions of the eye. Sufficiently good results have been obtained in such conditions as venereal lymphogranuloma, neuritis, arthralgia, myositis, acute and chronic infectious arthritis, acute rheumatic fever, chorea, undulant fever, meningococcal septicemia and asthma to warrant its further study. The contraindications are individual. Thirty different diseases have been treated by artificial fever at the Marine Hospital. The largest group, consisting of 567 patients, was that of gonococcal infections and their complications. Of 352 patients having five hour sessions at from 106 to 107 F., with an average number of 6.5 fever sessions, 304 received adequate observation and treatment and of these 252, or 82.5 per cent, recovered. Forty-two patients received sulfanilamide and, fail-

ing to respond to this, were given an average of 6.6 fever sessions at from 106 to 107 F. for five hours. Thirty-six of these were under adequate observation and treatment, and twenty-six, or 72.2 per cent, recovered. Of the 173 patients who received sulfanilamide or sulfapyridine and, failing to respond, were given an average of 2.6 ten hour sessions of fever at from 105 to 107 F. alone or with additional chemotherapy 156, or 94.5 per cent, recovered. In a follow-up study 275 of the 567 patients have been rechecked as to recurrence of gonorrhea. Of these patients 241 completed their treatment from one to five and a half years ago and thirty-four from three months to one year ago. Of the entire group, nine, or 3.2 per cent, had a recurrence. An additional eleven, or 3.9 per cent, were reinfectd. Encouraging results were obtained in a group of 129 patients having gonorrhoeal arthritis. Of these, 102 were markedly improved or recovered. A follow-up of fifty-two for from one to five and a half years showed that all except two had maintained their degree of improvement. Of 160 epididymal gonococccic complications all but five were promptly relieved by fever therapy. Ninety-eight cases of acute gonorrhoeal prostatitis showed excellent results from fever therapy. Excellent results were also obtained in gonococccic seminal vesiculitis, balanoposthitis, severe inguinal adenitis, periurethral abscess and pelvic inflammatory disease. Since no form of therapy in syphilis can be evaluated in five and a half years, which is the longest period that any of the 187 patients with this disease was observed, it is impossible to determine what the final results of fever therapy will be. Fever therapy combined with chemotherapy appeared to be of value in the treatment of dementia paralytica, tabes dorsalis, asymptomatic neurosyphilis, acute syphilitic eye conditions, arsenical intolerance and seroresistant syphilis.

Controlled Fluid Therapy.—Drew and his associates warn that in fluid therapy the hematocrit, the specific gravity and the plasma protein determinations should not interpret the state of dehydration without considering the history and the clinical picture of the patient. These procedures should aid, not substitute, other well established diagnostic procedures. Certain well defined patterns have recurred many times in a large series of such cases, and these have proved of great aid in the interpretation of the values of the aids in any specific case. In simple dehydration (whether from lack of fluid intake, diarrhea, excessive sweating, severe vomiting or shock of psychogenic, traumatic or postoperative origin) uncomplicated by hemorrhage there is a rise in the cell volume, the specific gravity of whole blood and of plasma and the protein percentage of plasma. In the first three of these conditions, treatment consists in administering fluids until these elevated values tend to approach normal. In shock, treatment to be rational must overcome the severe arteriolar and venular spasm, the capillary paralysis and dilatation and the great loss of circulating blood volume. Hypertonic sodium chloride is particularly effective in relieving the arteriolar spasm, in decreasing the viscosity of the blood and in aiding the return of fluid from the tissues into the circulation. It should be used cautiously in collapse due to dehydration. Adrenal cortex extract (eschatin) has proved valuable in restoring capillary tone, raising the blood pressure and redistributing electrolytes. To maintain any gain initiated by the sodium chloride and adrenal cortex extract blood transfusions are given as indicated by repeated blood studies. In hemorrhage there is an immediate fall in the specific gravity of the whole blood and a drop in the cell volume as determined by the hematocrit. The changes of the specific gravity of the plasma are less marked. Treatment consists of restoring blood volume by transfusions. It is of utmost importance to determine whether shock is complicated by hemorrhage or not. When not only loss of fluid but loss of protein exists, there is a tendency for the hematocrit curve to rise while the protein values continue to fall. In these cases the extreme hemoconcentration and shock must be combated by adequate administration of fluid, but the already lowered protein concentration must not be reduced to the edema level. When acute changes take place in chronic disease in which anemia already exists, and probably hypoproteinemia, any one of the ordinary tests—erythrocyte count, hemoglobin or hematocrit determination—will not evaluate the true state of hydration. A combination of all is necessary and particularly determination of the specific gravity of the plasma. Treatment consists in reducing the protein values to approximately normal levels and restoring the cellular elements of the

blood. Impending edema may be suspected by a gradually falling plasma protein level. When the hematocrit reading shows more than 60 per cent volume, it is unwise to give large quantities of hypertonic solutions, as this may bring into the circulation cell water rich in electrolytes, which is definitely toxic when present in the plasma in quantities greater than normal. The severely ill patient may not be able to utilize fluids of any type or quantity until the severe spasm of the peripheral vessels is relieved and the circulation of the sequestered blood in the paralyzed peripheral capillaries has returned. The only safe procedure is to measure the degree of hemoconcentration or anemia and the degree of dehydration or edema, institute the therapy suggested by the changes found, follow the curve of progress by repeated determinations and evaluate the state of hydration day by day or hour by hour if need be.

Tuberculous Empyema Thoracis.—Vineberg and Aronovitch state that patients with tuberculous empyema are often seen when operative procedures cannot be carried out. Prolonged, unsuccessful, palliative treatment is known to lead to a high mortality. There is a tendency to continue such treatment for months without benefit to the patient. The disease spreads, or the resistance is so lowered that more radical measures are impossible. Thirty-seven cases (2.2 per cent) of tuberculous empyema occurred in the authors' series of 1,371 cases. If the cases of artificial pneumothorax are not included, the incidence is reduced to 0.5 per cent. If only pneumothorax cases are considered, the incidence is 9.9 per cent. The development of a tuberculous empyema signifies the presence of a bronchopleural fistula. The longer the fistula remains, the greater are the chances of mixed pleural infection. Tuberculous empyema, like tuberculosis elsewhere, is not a static disease but one which is constantly changing. A tuberculous pneumonic disease is always associated with some infection of the visceral pleura. If the visceral and parietal pleural surfaces are in contact, this may result only in adhesions. When there is a large amount of exudation before adhesions are formed, the exudate collects in the pleural cavity as an empyema. If the pleural surfaces are separated, as in artificial pneumothorax, the exudate collects at the bottom of the pleural cavity, forming a pyopneumothorax. Pneumothorax predisposes to the formation of tuberculous empyema. In active pulmonary tuberculosis the most important preventive measure is the avoidance of effort, especially activities which cause sudden changes in intrapleural pressures. A sudden cough or straining effort may result in the rupture of an adhesion. Such adhesions may contain lung tissue or may rupture at their pulmonary attachments, thus creating bronchopleural fistulas. Adhesions under tension should be cut when possible. If pneumothorax is not efficient it should be abandoned and replaced by surgical collapse. If the pneumothorax is efficient it may be continued, but the activity of the patient should be drastically curtailed. The majority of their cases of tuberculous empyema developed in cases in which pneumothorax therapy was continued long after it should have been abandoned. Such continuance may result in spread of the disease from an uncollapsed cavity and/or tuberculous empyema secondary to ruptured adhesions and the resultant bronchopleural fistula. There were thirteen cases of unilateral pure tuberculous empyema complicating artificial pneumothorax. The duration of the pneumothorax to the time of onset of fluid ranged from nine days to sixty-five months. The time interval from the first appearance of fluid to the onset of empyema varied from two weeks to fourteen months and the period during which surgical intervention might have been beneficial varied from one month to two years. Surgical intervention is not as urgent in these cases as it is in those presenting mixed tuberculous empyema. Under conservative treatment several of these cases developed into cases of bilateral involvement and consequently became inoperable. Six of the cases were fatal, the course of the disease in three cases is downhill, in three the disease has been arrested and in one it is stationary. Of the arrested cases thoracoplasty was performed in two and one was cleared up by aspiration and air replacement. Two of the seven cases which became bilateral did so shortly after thoracotomy. There were four cases of unilateral mixed tuberculous empyema complicating artificial pneumothorax. The duration of the pneumothorax up to the time

of onset of fluid ranged from four to forty-eight months. Thoracoplasty could have been performed at the onset. In only one case did the period of operability extend to three months. All the patients died soon after the onset of the empyema—one within five weeks. Two of the four cases became bilateral; in one case a thoracotomy and phrenic exeresis were performed and the patient survived for one year. Of the twenty-seven cases of tuberculous empyema with bilateral involvement nine were unilateral when first seen; nineteen presented pure and eight mixed empyemas. In twenty-two cases empyema occurred during the course of artificial pneumothorax and in five it resulted from spontaneous pneumothorax. There have been seventeen deaths, the course in seven is downhill, in two the disease has apparently been arrested and one case has not been traced. In both of the arrested cases thoracoplasty has been done; one of these presented a mixed and the other a pure tuberculous empyema. It is significant that five of the six patients who were cured had undergone thoracoplasty. The authors are convinced that many of the patients would have been benefited by thoracoplasty had the procedure been instituted sooner.

Roentgen Therapy and Ovarian Physiology.—Rock and his co-workers used subcastrative doses of x-rays over the ovaries and pituitary in the treatment of twenty-seven patients with menstrual disorders with or without sterility. Twenty-two had proved anovulatory flow or flow which was predominantly anovulatory with occasional ovulatory cycles. No endometrium was obtained on repeated efforts from one woman, and this was presumed to be an instance of primary pituitary deficiency. Five patients had cyclic ovulation but with associated disturbances: sterility, polymenorrhea or hypermenorrhea. None of these five patients was relieved or cured. Twelve of the patients with faulty ovulation were cured, and the treatment of ten resulted in failure. If an ovulatory cycle could not be proved within three months after the completion of roentgen therapy the case was considered a failure. Patients considered cured were those in whom biopsies demonstrated ovulatory cycles three months or more after roentgen therapy, those of sterility in which pregnancy proved ovulation or those who acquired after treatment the molimina of menstruation with periodicity of characteristic flow. Three, or 13.6 per cent, of the patients became pregnant. The figures of cure are well above the most optimistic results reported from endocrine treatment alone. Many of the cured women were under endocrine treatment before roentgen therapy was tried. Regular ovulatory cycles began within from two to ten weeks following the first roentgen treatment. No apparent harm resulted when a subsequent series of treatments with the same dosage was given after an interval of from two or three months. Three doses, each from 50 to 60 roentgens, given over the ovaries seem harmless to the ovaries of women less than 35 years of age. Women older than this may suffer temporary or permanent cessation of follicular function. The authors believe that roentgen treatment of the pituitary offers no additional benefit. To explain the good results, they postulate a destruction by x-rays of persisting mature follicles, thus allowing a new cycle of follicle development and maturation to take place.

Parathyroid Function.—Helfet studied the theory that solution of parathyroid exerts its primary effect on the phosphorus metabolism and not on the control of the level of blood calcium. The theory suggested is (1) that solution of parathyroid controls the inorganic phosphate level of the blood, (2) it prevents this level from rising to a degree which would upset any metabolic process in which the phosphates are concerned, (3) that an accumulation of phosphate in the blood is a stimulus to increased secretion of solution of parathyroid, (4) that solution of parathyroid effects phosphate control by stimulating excretion of phosphate by the kidney and by mobilizing calcium ions from the storehouse in the bones and (5) that, vice versa, if the parathyroids are removed the body will be unable to deal adequately with the blood phosphate. It seems reasonable that in the treatment of generalized fibrocystic diseases and rheumatoid arthritis an attempt should be made to reduce the absorption of phosphorus and thus remove the stimulus to the overproduction of solution of parathyroid. A method for reducing phosphorus absorption consisted in giving daily an amount of aluminum acetate with a phosphate-combining power equivalent to from 150 to 220 mg. of calcium. Children were given a correspondingly smaller dose. A fourth of this daily dose was taken after each meal, so that the aluminum could combine with the phosphate of all food eaten during the day. Too large a

dose of aluminum acetate can produce rickets. No additional form of therapy was used. The patients were on their normal diets. In order to give them some source of calcium and vitamin D they took not less than 1 pint (0.5 liter) of milk a day. Undoubted improvement was produced in three of four cases of generalized fibrocystic osteitis, indicating that the phosphorus radical is responsible for the excessive stimulation of the parathyroids. The results of aluminum acetate therapy have been most encouraging in twelve cases of rheumatoid arthritis and three of spondylitis ankylopoietica. Some of these patients had previously received gold therapy or had a focus of sepsis removed, all without effect. Of these fifteen patients twelve improved in color, ten gained weight, nine were markedly relieved of joint pains and in two there was no improvement. The subsidence of symptoms in some joints was almost dramatic and, except for joints which were ankylosed when treatment commenced, motion improved. Two patients who had typical deformities of the fingers could, after four months of treatment, actively correct this. In some the spindle-shaped swellings of the finger joints disappeared, although no physical therapy was given. However such therapy, carefully supervised, should enhance the value of treatment with aluminum acetate. Eight patients suffering from Paget's disease improved in color and in weight on this therapy. They could walk farther and do more before fatigue set in. Bone pain became less frequent and less intense and in some cases disappeared. In two cases controlled roentgenograms suggested a slow change toward normality. There was less expansion, the outline of the cortex seemed more definite and the density of the bone was reduced. In spite of clinical improvement, there was no appreciable change in the roentgenograms of any other patient. The author hopes that the results are promising enough to open up a new field of investigation and a new line of treatment for these distressing diseases.

Sciatica and the Intervertebral Disk.—Pennybacker's report is concerned with thirty consecutive cases of sciatica treated in the Nuffield Department of Surgery, Oxford, since May 1939. Since all the patients were operated on within the past nine months, it is too early to speak of ultimate results. The most dramatic relief was obtained in twenty-one cases of severe sciatica in which a loose fragment of prolapsed nucleus pulposus was removed. Most of the patients began to walk seventeen or eighteen days after operation, and although there was some soreness and stiffness of the back at first this improved rapidly with graduated exercise, and by the end of a month the patients were free from symptoms. Of the five patients who had herniation of the annulus fibrosus, two experienced immediate relief and had a painless convalescence. In three others, the results of operation were not satisfactory. The two patients with the cauda equina syndrome were completely free from pain after operation, but recovery of sphincter control and of the sensory and motor functions has been slow. Of the remaining cases, one was a negative exploration, but the patient has benefited considerably from the laminectomy; in the other, a fibro-angioma was removed from the intervertebral canal, but this has not completely relieved the pain. In no case has there been any aggravation of the symptoms or neurologic signs after operation. It appears that operation is advisable in three groups of patients: (1) in cases of acute sciatica which send the patient to bed and in which, despite adequate rest for from five to six weeks, the severe pain persists; (2) in frequently recurring attacks, which may be severe enough to send the patient to bed or to make his life a misery for three or four weeks every year; (3) in some cases of chronic continuous sciatica due to a prolapsed nucleus pulposus, in which the results of operation are no less satisfactory than in the acute and severe cases. But others in this group will be due to a herniated annulus fibrosus, and the results in these have not been as uniformly satisfactory as in those due to prolapse of the nucleus pulposus. Until it is possible to differentiate these varieties by the history and examination, or by myelography, some doubt must remain about the value of operation.

- *Pathology of Liver in Children. P. Woringer.—p. 313.
Kernicterus of the Newborn. M. Péhu and M. Dollet.—p. 349.

"Lipogenic Dyshepatia" in Children.—Under this name Woringer discusses a minor liver disorder of children that receives scant attention in the textbooks. Frequently, though not exclusively, found in pampered children of preschool and school age, it involves the enlargement of the liver and is characterized by abdominal pain, nausea, vomiting, anorexia, pallor, headache, dipsois and the absence of fever. It is primarily due to a metabolic dysfunction and yields to a rational fat excluding regimen. However, other therapeutic aids may be employed advantageously. The sudden onset of the symptoms may confuse diagnosis. The significant factor is the size of the liver. Examined with the patient lying on his back, the head slightly raised and the knees flexed, the liver presents itself to the experienced touch as uniformly smooth and plastic, with a well defined edge but exceeding the dimensions of 2 cc. below the costal margin, accepted by the author as the norm for normal livers in children of that age. Pathologic enlargements of the liver may be found to attain to 9 cc. below the costal arch. Tests for bilirubin, albumin, sugar and acetone bodies are negative. Fats chiefly productive of hepatic dysfunction are egg yolk, cocoa butter in chocolate, animal fats and milk fats in the various forms. Different persons are affected differently by different fats. Vegetable oils were found to be less harmful; olive oil was proved to be useful in maintaining necessary fat metabolism. Hereditary diathesis, previous infectious diseases and sedentary habits may enter into the pathologic picture. Whereas symptoms may be promptly checked by correct diet, it may take several weeks and months before the liver returns to normal size. It may long require dietary supervision in order to protect it against recurrence. The author stresses the diagnostic value of correct liver palpation, offers a detailed dietary program and believes, on the basis of familial and other investigations, that a connection exists between unrecognized and neglected "lipogenic dyshepatia" and the evolution of biliary calculi in later life.

Determination of Reduction of Oxyhemoglobin in Blood of Living Human Subjects: New Method and Possibility of Its Use for Clinical Diagnosis. L. Rósa.—p. 328.
Treatment of Cervical Catarrh. W. Schellenberg.—p. 329.

Colposcopy and Prevention of Carcinoma of Os Uteri.—Hinselmann, whose experience with colposcopy covers a period of fifteen years, maintains that it is superior to ordinary speculum examination. The degree of superiority is dependent on the apparatus and the experience of the examiner. For routine use in every gynecologic examination he recommends a colposcope giving a 10.5 fold magnification. The inspection should be binocular and the distance from 14 to 19 cm. He distinguishes between simple and extended colposcopy. Extension of colposcopy involves (1) histochemical aids and (2) optical aids. In performing a colposcopy, the author uses the simple method with ordinary mixed light followed by monochromatic illumination. The acetic acid test is applied and the cervix again examined with the aid of the monochromatic illumination and once more with the ordinary light. Schiller's iodine test is followed by examination with monochromatic lights. In this extended form colposcopy requires more time than the speculum examination. Cornified atypical epithelium can be detected with a less than tenfold magnification; the diagnosis, however, of atypical epithelium without cornification or of cone formation is not possible with a fivefold magnification. Thus it is apparent that cases cannot be sorted out with low magnifications. Colposcopy complemented by the use of chemical reagents provides such conclusive evidence as to make numerous biopsies unneces-

sary. The detection of the early changes makes possible early treatment, thereby avoiding not only extensive operations but also the development of the advanced forms of carcinoma.

Electric Shock Therapy in Psychiatry.—Disadvantages of metrazol shock therapy induced Müller to try the electric shock therapy introduced by Cerletti and Bini. The convulsions are produced by means of an alternating current of from 400 to 800 milliamperes, a tension of from 60 to 130 volts and a passage time of from 0.1 to 0.5 second. A preliminary test determines the conduction resistance on the head of the patient. The level of the resistance serves as the basis for the computation of the shock dose, although there was no close relationship between the conduction resistance and the current strength necessary for the elicitation of a shock. Not only does the resistance differ individually but it changes in the same patient. The "shock dose" has a tendency to be constant or to increase slightly. It was usually between 80 and 110 volts. Increase in tolerance in the course of treatment rarely exceeded 10 to 16 volts. The tension should not be over 130 volts and the passage time of the current should ordinarily not exceed 0.1 second. If the voltage is inadequate for the production of a complete attack, the time may be increased to 0.2 second. The author employed electric shock therapy in thirty-two cases, the total number of shocks being 413. The author gained the impression that the method was not inferior to other methods of shock therapy. The electric shock therapy may be combined with insulin therapy for schizophrenic patients. The chief advantage of the electric shock is that it is free from the fright and anxiety associated with other forms of shock therapy. Patients who previously had received metrazol shock corroborated this. The author is of the opinion that the electric shock therapy may become preferable to other forms of shock therapy.

*Joint Analgesia in Orthopedics. L. Bitossi Coronedi.—p. 473.

Joint Analgesia in Orthopedics.—Bitossi Coronedi established in experiment that joint pain originates in the periarticular tissues and that it can be controlled by local infiltrations of a solution of procaine hydrochloride. He treated twenty-nine cases of joint stiffness due to such causes as prolonged immobilization in fractures, trauma, disease of the joint and especially gonorrheal arthritis by articular anesthesia combined with physical therapy. Physical therapy alone had previously failed. The treatment consisted of local infiltration with an 8 per cent solution of procaine hydrochloride in amounts of from 6 to 7 cc. The analgesic effect appeared within half an hour and lasted for several days. Analgesia of the joint was as effective and lasting when the infiltration was made of the periarticular tissues alone as when made into the periarticular tissues and into the joint cavity. The effects were diminished if the infiltration was made into the articular cavity only. Joint function, where stiffness was caused by painful contracture, was reestablished after one infiltration followed by mobilization. In grave cases of joint stiffness from immobilization, trauma or arthritis the combined treatment of repeated injections administered at long intervals up to a total of from two to four, and physical therapy gave satisfactory functional results in the majority of cases. The treatment failed in the presence of established anatomic alterations of the joint such as destruction of the cartilages or bony ankylosis.

*Nutritional Disturbances from Avitaminosis B. A. J. Aballi and A. Escobar Aces.—p. 91.

Nutritional Disturbances from Avitaminosis B.—Aballi and Escobar Aces studied avitaminosis B in sixty-three infants. There were typical or atypical symptoms of pellagra and beriberi with or without cutaneous lesions in forty-three and nutritional and gastrointestinal disturbances in twenty. The majority of the patients had moderate or acute gastrointestinal and nutritional disturbances which were controlled by proper diet combined with vitamin B therapy (vitamin B, nicotinic acid and vitamin B₁₂, either alone or combined). Enteric infections assume a severe character in the presence of avitaminosis and frequently

lead to grave and even fatal toxicosis. In the group of patients with acute or subacute avitaminosis B, thirteen died, four showed no change and twenty-five improved rapidly. The twenty-four patients who received early treatment made a quick recovery. The symptoms were readily controlled and the weight of the infants increased, on an average, 1 pound a week. Necropsy in ten cases revealed extensive microcystic colitis, fatty degeneration of the liver and serous hepatitis. Cases in which the mucosa of the small intestine was slightly edematous and the seat of small ulcerations were rare.

*Vitamin C in Liver Diseases. J. M. González Galván.—p. 644.
Malignant Endocarditis Lenta of Early Meningeal Form. L. Clatro Sagastume and N. J. Zurutuza.—p. 651.

Vitamin C in Liver Diseases.—González Galván observed that certain complications of liver disease are caused by avitaminosis C and can be improved or controlled by intravenous injections of vitamin C in doses of from 0.05 to 0.1 Gm. The results are satisfactory when the vitamin is administered along with the correct treatment of the disease. In the group of patients observed by him the vitamin C therapy controlled gastric hemorrhages due to liver insufficiency, increased the diuresis in ascitic cirrhosis, improved the general condition of patients in cases of hepatitis associated with avitaminosis and favorably modified the course of toxic hepatitis. To obtain satisfactory results the treatment should be given over an extended period. The treatment does not influence the course of ascitic cirrhosis of the liver. The diuretic effects on the edema and the general condition of patients with ascitic cirrhosis are transient.

Repeated Development and Perforation of Peptic Ulcer of Jejunum After Anterior Antecolic Gastro-Enterostomy with Braun's Anastomosis. M. Matyas.—p. 474.

Surgical Treatment of Pancreatic Cysts.—Kafka describes two cases of pancreatic cyst. A woman aged 58 with a pseudocyst was treated by means of a primary pancreaticocystogastrostomy. The healing tendency seemed favorable, but the patient succumbed to a sudden hemorrhage into the intestinal tract on the ninth day after the operation. The second patient was a woman aged 56 with a pseudocyst. The first intervention resulted in a fistula and a cavity in the pancreas. A subsequent pancreaticocystojejunostomy resulted in a complete cure. The author reviews the various surgical methods and evaluates the various types of anastomosis. These operations were palliative and were regarded free from danger. The fatal outcome in one of the author's cases demonstrated the possibility of complications which may arise from the anastomosis of a pancreatic cyst with the intestinal tract. The author advises against a primary anastomosis of the cyst, particularly with the stomach. Such an intervention would be permissible only in the form of Jedlick's operation; that is, a lateral pancreaticogastrostomy with external drainage of the residual cavity. Otherwise, marsupialization is to be preferred. A persistent fistula may be anastomosed with the gastrointestinal tract. If x-ray examination or laparotomy reveals, in addition, a residual cavity, it may be treated by a wide cystenterostomy, in which the danger of obliteration of the stoma does not exist to the same extent as in the presence of a simple anastomosis of the fistula with the digestive tract.

Renal Hemangiomas.—According to Pitrolffy-Szabó, hemangiomas of the kidneys are rare, only three cases having been detected among 251 renal tumors at the urologic clinic of the University of Budapest. One of these tumors was very small and had unusual localization. A decapsulation for a

localized nephritis, suspected because of a persistent hematuria, failed to disclose the cause of the bleeding. Continued hematuria and increasing anemia necessitated a nephrectomy. Inspection of the pelvis of the kidney after formaldehyde fixation disclosed a protrusion of the mucosa twice the size of a pinhead. Sectioning revealed in the wall of the renal pelvis a structure dissecting the muscular layer, which consisted of blood-filled cavities separated by septums of connective tissue. The lumens were filled with erythrocytes. Since the substance of the kidney showed no change that could have been responsible for the hematuria, this extremely small cavernous hemangioma must have been the source. In the second case a cavernous hemangioma the size of a hazel nut was discovered in the region of a papilla near the upper pole. The third patient had a cavernous angioma on the posterior surface of the left kidney, which penetrated into the renal tissue to a depth of 1 cm. Renal hemangiomas always require surgical intervention. Decapsulation is unsatisfactory because it often has to be followed by nephrectomy. Nephrotomy is valuable chiefly for the diagnosis, although it may also permit the removal of a hemangioma in a renal papilla. It may, however, be followed by postoperative hemorrhage. The author therefore considers nephrectomy preferable for renal hemangioma. Diagnosis is possible only after exposure of the kidney because hematuria is frequently the only symptom and pyelography fails to disclose the source.

Breast Carcinoma.—Derra and Blittersdorf analyzed the results in 313 cases of malignant mammary tumors (308 carcinomas and five sarcomas) treated at two hospitals in Bonn from 1928 to 1935. The 308 cases of carcinoma comprise 180 treated for the first time, seventy-nine treated for recurrence and metastases and forty-nine hospitalized for prophylactic postoperative irradiation after surgical treatment elsewhere. Investigations on the etiologic significance of hereditary predisposition, trauma, mastitis, generative capacity and goiter were negative. There was a noticeable increase in the number of patients who asked medical advice during the first three months and a decrease in those who had waited longer. The treatment of choice was the radical operation. Palliative operations were not always avoidable. The total surgical mortality was 5 per cent, that of the radical operation 4.4 per cent. The length of survival was good. Results were poor in the seventy-nine cases of recurrence and metastases. Recurrence took place in approximately 80 per cent of the cases during the first three years, but a definite estimate regarding recurrence is possible at the earliest after five years. Recurrence took place as late as eleven and fourteen years after the primary operation. Postoperative irradiation did not improve the therapeutic results. The suggestion has been made that the tumor be extirpated and the regional metastases combated by roentgen irradiation. This point of view is to be deplored. The present survey gives support to the rationale of the radical operation. The earlier it is performed, the better are the results.

*Vitamin B₁ Tolerance Tests. S. Molnár and M. Horányi.—p. 204.

A Plea for More Rapid Centrifuges. W. Schmidt-Lange.—p. 206.

Vitamin B₁ Tolerance Tests.—Molnár and Horányi tested the vitamin B₁ metabolism of thirty-two patients and nine controls by observing the increase of this vitamin in the blood after injection. The clinical pictures of twenty-four of these were those of ulcer, malignant tumor, cachexia associated with a continuous high pyrexia, and exophthalmic goiter. The procedure employed was a preliminary test of the vitamin B₁ content of the blood, followed by an intravenous injection of 1,000 micrograms of vitamin B₁, an amount equivalent to the normal daily need of a healthy person. The vitamin B₁ blood level was then measured successively after five, ten, fifteen, thirty and sixty minutes. Concurrently, the vitamin B₁ level in the urine

was examined for three hours after the injection. Comparison of the vitamin B₁ level in the blood of the two groups disclosed a scarcely appreciable increase in the clinical cases, the average amounting to 28 micrograms per hundred cubic centimeters as compared with a 10 microgram average in the control group. The presence of vitamin B₁ in the urine was likewise lower than in the control group, but no conclusions could be based on the percental differences. Special tests were made on six patients: three with ulcers but without B₁ deficiency, two with pernicious anemia and one with afebrile panmyelophthisis. Vitamin B₁ deficiency in ulcer cases was found to be due not to a specific cause but to vitamin B₁ impoverishment inherent in the special diet. No vitamin B₁ deficiency was observed in the three other cases. Additional tests made in two cases of Addison's disease produced contradictory results. The author believes that most of the injected vitamin B₁ which is not accounted for in the blood or urine is converted into cocarboxylase and either passes into the blood stream or is deposited in the tissues.

Intra-Abdominal Hemorrhage in Myomatous Uterus During Delivery. K. Jäger.—p. 443.

Successful Operations for Thrombi: Two Cases. W. Schmidt.—p. 446.

Ovarian Dysgerminoma.—Dysgerminoma ovarii occupies a unique place among ovarian cancers because, unlike granulosa cell tumor or arrhenoblastoma, it does not possess a hormonal function. Eighty-five cases have thus far been observed. Dysgerminoma originates in the not yet differentiated germinal epithelium and, like the original tissue, does not exert a hormonal effect. The germinal epithelium loses the capacity to become differentiated and does not tend in the female, male or hermaphroditic direction but in an asexual one. The tumors vary in size between hardly visible ovarian infiltrations and giant tumors. The cells are fragile and exhibit extremely active karyokinesis. Metastases take place into the pleura, the omentum, the peritoneum and the other ovary. The rapid growth, the metastases and the relapses indicate an unfavorable prognosis. Kramberg reports that a woman aged 24 presented a history of amenorrhea followed eighteen months later by visible abdominal enlargement. A hemorrhage of four weeks' duration called for operative intervention and removal of a dysgerminoma of the right ovary weighing 2,300 Gm. There were no metastases or enlarged lymph nodes. She was given roentgen and radium radiation. At a follow-up examination a year after she was well.

Exanthematous Typhus.—Kramer directs attention to the increased danger of outbreaks of exanthematous typhus under the present war conditions in Europe. He reproduces a map showing its incidence during 1939 in the countries of eastern Europe, particularly Poland. This eastern European exanthematous typhus is the true louse typhus; that is, it is transmitted by body lice, the digestive tract of which harbors *Rickettsia prowazekii*. The author reviews the clinical aspects, citing his own observations in the course of the epidemic of 1919 in Rotterdam. He stresses the difficulties encountered in the differentiation of exanthematous typhus from typhoid and from meningococcal septicemia. Delousing and active immunization are the most powerful weapons against exanthematous typhus. Its treatment is symptomatic, neither chemotherapy nor convalescent serum having produced therapeutic results.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JANUARY-JUNE 1940

Titles have been listed or Abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1930. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2660.

Georgia and Maryland) 1563—OS; (Buenos
Aires) 1944; (lowest rate, U. S.) 2316
mortality, session on, at Chicago Medical So-
ciety, 1467
objectives (10) in preventive medicine appli-
cable to, 1128—SS
precocious puberty in due to adrenal tumor,
[Fraser] 1967—ab
premature, after-history, especially effect of
birth weight, [Hillingsworth] 449—ab
premature, Brucella abortus infection in,
[Buser-Plüss] 2259—ab
premature, prothrombin in blood, micro pro-
thrombin tests for, [Kato & Poncher] *749
premature, reunion at New York Fair, 2315
pyloric stenosis in, surgical treatment, [DI-
khulzen] 290—ab
pylorotomy in, gastric peristalsis after, [DI-
& Davis] *847
smallpox vaccination on back, 2494
"Test-Tube Baby": See Impregnation, arti-
ficial
toxemia, plasma transfusion in, [Dost] 2067
vitamin K deficiency, [Dam] 531—ab
Weight: See Infants, premature; Infants,
Newborn, weight
who died because of failure to get physician;
Randolph case, 589—E
INFANTS, NEWBORN: See also Fetus
anemia of, [Dwyer] 2256—ab
Asphyxia of: See Asphyxia
blood in, prothrombin content, micro pro-
thrombin test, [Kato & Poncher] *749
bones (long) in, of mothers given bismuth,
[Whitridge] 2147—ab
care, preventive pediatrics, [Davison] *742
cyanosis and hyperpyrexia fatal in, 1577
diarrhea in, pectin-agar for, [Howard &
Tompkins] *2355
duodenoduodenostomy for atresia at duodeno-
jejunal junction, [Stetten] 2415—ab
emergencies, [Brennemann] *956; [Brescia]
2139—C; [Irenemann] 2140—C
feeding, human milk contain sufficient vita-
mins (especially C and D)? 1287
gonococcal arthritis, sulfanilamide for, [Par-
rish & others] *241
heart murmurs in, [Lyon] 2253—ab
hemorrhage from umbilical cord fatal, 2324
hemorrhage in, role of vitamin K, [Waddell]
696—ab
hemorrhagic disease, delayed restoration of
prothrombin level, [Quick] 1014—ab
hypoparathyroidism in, [Pincus & Gittleman]
1005—C
malformations reportable, Germany, 2318
pneumothorax (spontaneous) in, [DeCosta]
2501—ab
sclerema, [Wells] *2288
smallpox vaccination with culture vs. calf
lymph virus, [Donnelly] 1293—ab
- INFANTS, NEWBORN**—Continued
sulfanilamide dangerous to? 1271—E; [Pratt
& Stewart] 1687—C
survival of 2½ pound unclothed infant ex-
posed to severe cold all night, [Lucas] 179
—C
tetanus in, treatment [Ferrari] 2066—ab
weight at birth, control by giving thyroid
extract in pregnancy, [Arnold] 1110—ab
INFECTIOUS DISEASE: See also Communi-
cable Disease; under names of specific in-
fectious diseases
Focal: See also Mouth; Teeth; Tonsils
focal, and systemic disease, [Reimann &
Havens] *1

Jour. A. M. A.
JUNE 29, 1940

- LABELS** of vitamin-containing alcoholic beverages, 1671—E; [Newell] 2489—C
- LABOR**: See also Abortion; Hospitals, maternity; Midwives; Obstetrics; Puerperium; "Childbirth"; under Medical Abstracts at end of letter M
- afterpains**, testosterone propionate for, [Abaranel] 525—ab
- Anesthesia** in: See Anesthesia in obstetrics
- Beck** many failed binder in, [Procter & Dickinson] *384
- complications**, anterior pituitary necrosis [Gotshalk & Tilden] *33
- C**; [Spalding] 1284—C; [Waters] 1391
- dry**, newer concepts, [King] *238
- infections** after: See Puerperal Infection
- pains** (weak), estrogens in, [Kepp] 451—ab
- pituitary** (posterior) solution in, sensitivity to, [Brewer] 678—C; (turticaria) [Abbott] 821—C; [Paolazzi] 823
- Postpartum Urinary Suppression**: See Puerperium
- Postpartum Uterine Inversion**: See Puerperium
- Premature**: See Infants, premature
- presentation**, breech, cause, [Vartan] 2258
- ab**
- presentation**, breech, fetal death with liver rupture in, 2404
- presentation**, occipitoposterior, version, [Proctor & Dickinson] *381
- LABORATORIES**, hormone research, opened by second stage, normal duration, 79
- Zondek**, 2398
- clinical research** relation to, 2552—E
- service**, emergency public health, England, 1384
- state**, A.M.A. resolution on limiting type and extent of services, 2478—OS; 2558—OS
- state**, American Society of Clinical Pathologists memorandum, 665—OS
- state** (new), dedicated, North Carolina, 1468
- technicians**, clinical, registry for; American Medical Technologists, 1269—E
- *1263**; 1269—E
- technicians**, second annual institute, 1382
- technicians**, state laws on, [McDavitt] 976
- OS**
- LACTATION**: See also Milk, human; Nipple
- Hormone**: See Prolactin
- inhibiting**, stilbestrol for, [Wenner] 2342—ab
- inhibiting**, triphenylchloroethylene for, [Macpherson] 1023—ab
- intervals** between nursing effect on fat in milk, [Ruzicic] 362—ab
- menstruation** in mother affect baby? 514
- neurtitis** (so-called), [Glees] 1027—ab
- LACTOSE** U.S.P., Merck Milk Sugar, 1557
- LA FRANCE** Inhalator, 961
- LAHEY**, FRANK HOWARD, president-elect, 2464—E
- LALDLAW**, PATRICK, death, 1820
- LAKE** George Foundation: See Foundations
- LAMBLIASIS**, giardiasis, [Veghelyi] 2331—ab
- LAMP**: See Sunlamps; Ultraviolet Rays
- LANCASTER** Test: See Vision
- LANDIS** Method: See Vision
- LANE**, COOPER, early diathesis, hemorrhagic California, 1669—E
- LAPAROTOMY**: See Abdomen surgery
- LARYNGITIS**, pediatric emergency, [Brennemann] *958; *959
- Tuberculous**: See Larynx, tuberculosis
- LARYNGOLOGY**: See also Otorhinolaryngology
- American Laryngological Association**, 1941
- LARYNGOSCOPY**, direct, indications, [Jackson] 828—ab
- LARYNGOTRACHEITIS**, pediatric emergencies, [Brennemann] *959
- LARYNX**: See also Laryngitis; Laryngoscopy; etc.
- cancer**, fenestration method for, 999
- cancer** in first 3 decades, [New] 1021—ab
- surgery** (restorative) after partial extirpation, [Brünlings] 453—ab
- tuberculosis**, diagnosis; treatment, [Looper] 2420—ab
- ATERAL SINUS**, increased intracranial pressure from venous obstruction, [Ecker & others] *1440
- ATIN AMERICA**, relations in medical education and licensure, [Bierling] 1580—ab
- TRINES**: See Tolls
- UNDREY**, irritant on clothes from; use of neutralizing sour, 1286
- W**: See also Harrison Narcotic Act; Legislation; Workmen's Compensation Acts
- and crime**, 1277
- ATTIVES**: See Cathartics
- MEN'S League Against Epilepsy**, 1277; [Lennox] *1354; (announce 2 annual awards) 1942
- LEAD**, absorption through skin, 604
- encephalopathy**, surgical decompression treatment of, [Haverfield & others] *2432
- free** crayon chalks, 81
- in food** and plant sprays, tolerance for, 1008
- ingestion** of 0.18 to 0.3 mg daily in average diet, [Kehoe] 438—ab
- Poisoning**: See also Medical Abstracts
- at end of letter M**
- poisoning** (acute) from toy dishes, [Rathmell & Smith] *242; (question of antimony) [Aub] 2237—C
- poisoning** and juvenile nephritis in Australia, 1753—E
- poisoning** (chronic), ascorbic acid in, [Dannenbergh & others] *1439
- poisoning**, encephalopathy, [Haverfield & others] *2432
- poisoning** from nipple shields in infants, 274
- poisoning** hazard of storage battery industry, study of in Illinois, 420
- poisoning** in roofers, [Magnuson & Raulston] *1528
- poisoning** (latent), bismuth for, [Epstein] 694—ab
- poisoning** relation to parkinsonism, 79
- retention**, calcium and phosphorus effect on, [Lederer & Bing] *2457
- tetra-ethyl**, industrial dermatitis from "glove phytids," [Norwood & Evans] *1523; [Verstandig] 2237—C
- toxic** dosage (minimal), 2490

- MEDICOLEGAL ABSTRACTS
ABORTIONS, CRIMINAL: evidence; opinion
of experts as to instrument used admissible,
352
evidence; statements of woman as to cause of
abortion, 352
ADVERTISING: dental; legislative regulation
valid, 1488
dental; revocation of licenses, 1587
ANAPHYLAXIS: antitoxin serum; hyper-
sensitivity not a bodily injury, 1291
to, 2655
ASESTHETICS: ether; pneumonia in relation
to, 2655
ARSPHENAMINE: insurance, accident, in rela-
tion to death from neoplasmin, 918
BLINDNESS: definition in relief act unnece-
sary, 437
medical examiner: determination of blindness
by; constitutionality, 437
- admission in relation to, 1480
BLOOD VESSELS: aorta; rupture of in rela-
tion to, 2411
BOOKS: medical; commercial use of excerpt
medical; right of privacy, 518
medical; excerpt used for commercial pur-
poses, 518
CHILD BIRTH: See also Malpractice
unborn infant injured; liability for, 437
CHIROPODY: licenses, revocation; isolated
violations of medical practice act, 1587
CHIROPRACTIC: See also Malpractice
colonic irrigations; right to
diets; right to prescribe, 826
admission, 826
licenses; revocation; attorney general as com-
plaint, 1405
licenses; revocation; complaint, amendment
of, 1405
licenses; revocation; complaint charging sev-
eral unrelated offenses, 1405
licenses; revocation; discretion of board;
abuse of, 1405
licenses; revocation; "unprofessional con-
duct," 1405
physical therapy; right to practice, 826
radio broadcasts; breach of contract by radio
station, 1833
COLLEGES: See Schools
COMPENSATION OF PHYSICIANS: contracts;
promise of cure, 1291
corporations; officer's right to bind principal
to pay, 1832
cure, promise of; incurable disease, 1291
employer; liability when services rendered
at request of, 86
incurable disease, 1291
Hens, medical; compromise of damage suit as
affecting, 698
reasonableness; capability and renown of
physician, 280
reasonableness; competency of witness to tes-
tify, 280
reasonableness; criteria of, 280
reasonableness; income of physician; evidence
of admissibility, 280
reasonableness; wealth of patient; evidence
admissible, 280
third person; liability when services rendered
at request of, 86
CONTRACTS: See also Compensation of
Physicians
hospitalization contracts; assignability, 1107
hospitals; agreement not to operate; solici-
tation of patients, 1107
medical services; assignability, 1107
COPYRIGHT: medical books; excerpt used
for commercial purposes, 518
no rights contrary to law, 1012
dentistry; right to practice, 1012
hospitals; right to practice medicine, 1107
medical services to employee; officer's right to
bind principal, 1832
DEAD BODIES: solicitation of by under-
takers; revocation of licenses, 608
DEGREES: medical; denial of degree because
of misrepresentations, 436
DEMENTIA PARALYTICA: See Syphilis,
paretic
DENTAL PRACTICE ACTS: advertising; as
dishonorable conduct, 1587
advertising; legislative regulation of valid,
1488
clinic operated by college; recoupment of
overhead expenses from patients, 1093
corporate charter confers no right to practice
dentistry, 1012
corporations; right to practice dentistry, 1012
enforcement; injunctions, 1012
licenses; revocation; advertising, 1587
licenses; revocation; conclusive of board
findings, 1587
licenses; revocation; unethical practices, 1587
"licenses"; synonymous with "certificates,"
2330
overhead expenses; recoupment of as con-
stituting fee, 1693
profession; dentistry not a business, 1012
DIATHERMY: See Malpractice
DISEASE: See also Particular diseases
idiosyncrasy not a disease, 918
DRUGS: bish phenylmercuric nitrate; patent
invalid, 187
"patent medicine" construed, 2111
"proprietary medicine" construed, 2111
DYES: hair; eye injury attributed to, 2330
ERYSIPELAS: insurance, accident, in relation
to, 1955, 2215
EVIDENCE: See also Abortion, criminal;
Malpractice; Privileged Communications
complaints and statements; of patients, 352
need for non-treatment purposes, 1489
hospital records; statements as to cause of
abortion, 352
judicial notice; He detectors, reliability of, 86
He detectors; judicial notice of reliability, 86
witnesses, expert; opinion based on experi-
ments of others, 2111
witnesses; expert; opinion based on experi-
ments, 352

Medicolegal Abstracts—Continued**EVIDENCE—Continued**

witnesses, expert; opinion based on statements of person examined for non-treatment purposes, 1489
witnesses, expert; opinion invading province of jury, 2411
EYEGLASSES: fraudulent sale by impostor, 918

LIE DETECTOR: judicial notice of reliability, 86
LIENS: hospital; failure timely to file notice, 352
medical; compromise of damage suit as affecting, 608
MALPRACTICE: actions; limitations of; retroactive effect of act, 437
after care of hospital patient; liability for negligence, 684, 1694
anesthetics; necrosis following local administration, 2246
burns; roentgen rays, 1108
cervical canal; closure after conization operation, 684
childbirth; after-care, negligence in, 1694
childbirth; puerperal infection; negligence in treating, 1694
chiropractors; hemorrhoids treated surgically, 1405
chiropractors; standard of care required, 1405
chiropractors; surgery, right to practice, 1405
circumcision; necrosis following local anesthetic, 2246
concealment of facts from patient, 2145
conization operation; failure to prevent closing of cervical canal, 684
dentist; jawbone fractured in extraction of tooth, 1291
dentist; necessity for expert evidence, 1291
diagnosis; mistakes in, 437
diathermy; administration by technician, 2145
evidence; res ipsa loquitur; necrosis following local anesthetic, 2246
evidence; witnesses, expert; conclusiveness of testimony, 2529
evidence; witnesses, expert; contiguous localities; effect on qualification of witness, 188
evidence; witnesses, expert; familiarity with local standards necessary, 188
evidence; witnesses, expert; invading province of jury, 2329

MALPRACTICE—Continued

evidence; witnesses, expert; necessity for, 1291
foreign bodies; skin clips; limitation of actions, 188
fractures; casts; choice of cast determinable by physician, 2145
fractures; casts; removal of justified, when, 2145
fractures; extraction of tooth resulting in fracture of jawbone, 1291
fractures; non-union; age of patient an element, 2145
gas gangrene following treatment of hand injury, 2498
hemorrhoids; chiropractor's treatment of, 1405
hospital patient; after care required, 684, 1694
idiosyncrasy; roentgen rays, 1108
mastoidectomy; facial paralysis following, 2329
paralysis; facial; mastoidectomy in relation to, 2329
pregnancy; mistaken diagnosis, 437
prenatal injuries; liability for, 437
roentgen rays; burns; therapeutic use, 1108
roentgen rays; idiosyncrasy, 1108
skill and care; standards; by which non-sectarian practitioner judged, 1108
skill and care; standards; by which sectarian practitioner judged, 1405
skill and care; standards; by which specialists judged, 1108
skill and care; standards; in similar communities as criterion, 684
skin clip left in patient; limitation of actions, 188
specialists: skill and care required, 1108
statute of limitations; physician-patient relationship; termination as effecting statute, 188
statute of limitations; retroactive effect of, 437
tumor, uterine; pregnancy mistaken for, 437
uterus; removal; necessity for, 684
workmen's compensation in relation to, 2056
MEDICAL BOOKS: See Books, medical
MEDICAL COLLEGES: See Schools, medical
MEDICAL PRACTICE ACTS: chiropradist; practice of medicine by, 1587
chiropractic; diets, prescribing of, 826
chiropractic; physical therapy in relation to, 826
chiropractor; practice of medicine by, 826, 1587
colonic irrigations as practice of medicine, 826
corporations; hospital's right to practice medicine, 1107
diets; chiropractor's right to prescribe, 826
evidence; naturopathic association's charter, 685
examining boards; judicial powers of, 608
exceptions; need not be negated, 685
hospitals; corporate practice of medicine, 1107
licenses; revocation; judicial powers of board, 608
naturopathy; charter of state association as evidence, 685
physical therapy; chiropractor's right to practice, 826

SEKOV obesity cure 1578
SELENIUM problem, progress in, 1083—E

SUBJECT INDEX

JOUR. A. M. A.
JUNE 29, 1940

- SEMP'S Operation: See Tuberculosis, Pulmonary, thoracoplasty
SEMEN: See Spermatozoa
SEMIADOPTION: See Impregnation, artificial
SEMMELEWIS, IGNAZ PHILIPP, spiritual portrait, 1281
SENILITY: See Old Age
SENSATION: See Paresthesia
SEPTICEMIA: See Bacteremia; Bacteria funguliformis; Haverhillia; Staphylococcus; Medical Abstracts at end of letter M
SEREMY'S Test: See Cancer diagnosis
SEROBACTERINS-Mulford (Sharp & Dohme), 1453
SEROLOGICAL: See Cancer; Frambesta; Syphilis
SEROLOGOSIS, polyserositis or Pick's disease? 2190
SEROLOGOSIS: See Blood Transfusion; Diphtheria; Hemotherapy; Jaundice, splenic; Peritonitis; Sclerosis multiple; Tuberculosis, etc.
SERUM: See also Biologic Products; Vaccine
Adult: See Measles, prevention
Blood: See also under various headings of blood, (4-times concentrated) as diuretic in nephrosis, [Aldrich & Boyle] *1062
Contralescent: See Parotitis; Pityriasis rosea; Polymyositis; Rheumatic Fever; Scarlet Fever; Typhoid
human, American Human Serum Association, 2229
human, as blood substitute in hemorrhage and shock, [Levinson & others] *455;
Human Serum Laboratory, gift to Minnesota Medical Foundation, 594
Lymphatic: See Blood proteins
Plasma (clarified) in secondary shock, [Strumila & others] *1337
Pregnant Mare's: See Gonadotropins
Rabbit: See Pneumonia treatment
Shock: See Anaphylaxis and Allergy
Therapy: See Serotherapy (cross reference)
Toxoid Treatment: See Diphtheria
Transfusion: See Blood Transfusion
SERVANTS: See Domestic Servants
SEWAGE, polymyositis virus in, 112-E; [Ellsworth] 1020-ab; 2232
SEWALL, Lecture: See Lectures
SEX: See also Fertility; Impotence; Impregnation; Sterility
Anesthesia: See Anesthesia, sexual
determination by sex hormone assay, [Frank] *1507
Frigidity: See Frigidity
Function, Decline of: See Climacteric; Menopause
Function, Development of (Puberty): See Adolescence
Glands: See Gonads
Hormones: See also Androgens; Estrogens; Gonadotropins; etc.
hormones (female) in hemophilia, 1479
hormones, physiologic significance; use in practice, [Frank] *1504
inhibitions in the unmarried, problem of, [Barrow] *709
ratios in families with hemophilia, [MacKinnon] 523-ab; 1671-E
research in, National Research Council grants for, 813
SEXOL, Tablets, 1097-BI
SEXOL Chemical Company, Benacol Solution in pruritus ani, 1951
SHAMPOO soap (liquid), 2324
SHARP & DOHME Serochemicals, 1453
SHAVING, electric, no danger from inhaling hair in, 1008
SHERMAN Anti-Trust Act, indictment of A.M.A. under: See American Medical Association, U.S. Department of Justice indictment
SHIVERING: See under Cold
SHOCK, Allergic: See Anaphylaxis and Allergy
blood count in, 1577
Convulsive: See Dementia Praecox; Insulin shock; Tabes dorsalis; etc.
effect of picrodrol on circulatory collapse, [Kunkel] 190-ab
effect on direct arterial and venous pressure, [Volpito] 1111-ab
Electric: See Electric
Electric Therapeutic: See Dementia Praecox; Mental Disease
Serum: See Anaphylaxis and Allergy, serum
symptoms at Columbia, 1722-SS
traumatic, 2481
traumatic, circulatory failure, [Moon] *1313
treatment at Cook County Hospital, [Seed & Fantus] *2010
treatment, citrated plasma in, [Strumila & others] *1337
treatment, controlled fluid therapy, [Drew] 2397-ab
treatment, human serum as blood substitute in, [Levinson & others] *455; [Necheles] 520-ab
War Neuroses: See Neurosis
SHOES, [Ober] *1533
trench foot and, 1471
SHOT: See BB shot
SHOULDER: See also Scapula
dislocation (bilateral) in twins; familial tendency, [Magnuson & Stack] *2103
dislocations (recurrent), 513
tendon rupture, arthrography in, [Lindblom] 1300-ab
SHOVELER, fracture in, [Hall] 1019-ab
SHRIMP, tolerance for lead and arsenic in, 1008
SICKNESS: See Disease
Insurance: See Insurance, health
SILICOSIS: See Pneumoconiosis; Medical Abstracts at end of letter M
SILK as suture material, 2322; [Meade] 2510
SILVER Foll: See Burns, treatment
Seal Pain Relief Tablet, 1283-BI
Therapy: See Gonorrhea
toxicity, argyria from intranasal use, [Bryant] 1017-ab
toxicity, damage to lung tissue from intranasal use, [Parkinson] 678-C
SIMS, J. MARION, speculum in retrodisplaced uterus, [Parks] 1637-C
SINUS, Carotid: See Carotid Sinus
Lateral: See Lateral Sinus
Phonoid: See Lateral Sinus
SINUSITIS, NASAL: See also Maxillary Sinusitis
hyperplastic, in allergy, [Grove] 2252-ab
treatment, dangers of cocaine nasal spray, 80
treatment in children, [Mitchell] 1118-ab
treatment, roentgen, [Flint] 692-ab; [Gatewood] 1492-ab
SITUS Inversus: See Viscera transposition
SKIN: See also Dermatology; Tissue
absorption and permeability to 6 different fats, [Eller] 283-ab
absorption of hormones and vitamins in cosmetics, [Eller & Wolff] *1865; 1886-E;
absorption of lead and arsenic, 604
benzopyrene effect on, [Cottrell] 87-ab
cancer, diagnosed clinically; radium, x-rays, surgery; etc. for, [Warren & others] *1619
Disease: See also Acne; Dermatitis; Eczema; Urticaria
Disease, Industrial: See Industrial Dermatology
"load-skin"; "goose-skin" in A. avian disease, [Lehman & Rapaport] *386
Eruptions: See Eruptions
Fistula: See Fistula, gastrocutaneous
fluorescence microscopy and capillaroscopy, [Schmidt-La Baume] 1602-ab
Fungus infection: See Mycosis, cutaneous
Gonorrhea: See Keratosis blennorrhagica
graft (autogenous) of fibrosarcoma, [Harrill] 1492-ab
graft, treatment of avulsed flaps, [Farmer] 189-ab
grafted, sweating function, [Conway] 449-ab
iron deposits removal from, after using copernic, 431
Itching: See Pruritus
Mucor infection: See Mycosis, cutaneous
Reaction: See also Skin test; Tuberculin reaction (delayed) to brucellergen [January & Greene] *486; [Harris] 1099-C;
[Flannery] 1284-C
reaction in sulfathiazole therapy, [Haviland] 2505-ab
sulfanilamide excreted by, [Cornbleet] 2594
temperature, nicotinic acid and related compounds effect on, [Dean] 439-ab
Test: See also Skin reaction
Test (Francis): See Pneumonia, diagnosis
test (intradermal and scratch) in children, 913
Test (Patch): See Tuberculin
test, preparing fungus extracts for subcutaneous injection, 2492
Transplant: See Skin grafts
tuberculosis fungosa scirrhosa, [Hamann] 1603-ab
tuberculosis, long vs. short ultraviolet rays for, [Küller] 1027-ab
tumors, hemangiomas, [Ward & Covington] *2069
tumors, primary xanthomas and melanomas, [Foot] 411-ab
SKULL: See Cranium
SLEEP disorders, attacks of wakefulness in disorders, metrazol for intoxications from soporifics, [Heinrich] 627-ab
SMALLPOX epidemics in German history, 267
in Argentina, 2485
prevention and control in schools, 1673-OS
treatment, sulfanilamide, [Perna] 931-ab
vaccination of newborn with culture vs. calf lymph virus, [Donnelly] 1293-ab
vaccination on infant's back, 2491
vaccination, prognostic sign of "take," [Cohen] 1114-ab
vaccine, treatment of herpes, [Davis] *2098
SMOKE, SMOKING: See Tobacco
SNAKE bite, treatment, 2406
venom, effect on sugar in blood, 425
venom (moccasin) [Peck] 1114-ab
venom, need for careful verification of foreign abstracts, [Macht] 77-C
Venom Solution (moccasin) (Lederle), Council report, 2218
venom, treatment of hemophilia, 1470
SNEEZE Gas: See Diphenylamine chlorarsine
SNELLEN Charts: See Vision
SOAP, A. M. A. Advisory Committee on Advertising of, 1894-OS
use of neutralizing soap, 1286
Industrial dermatitis and, [Klauder] 1111-ab
shampoo (liquid), formula for, 2324
SOCIAL, environment for school children, 1673
hygiene, American Social Hygiene Association, (meeting on venereal disease control) 263;
(Social Hygiene Day, February 1) 337;
(experiments on 5-day treatment of syphilis) 2483
hygiene, requirements for specialists in Belgium, 1091
implications of licensure program, [De Lancy] 1581-ab
reform scheme for mixed colored population in West Indies, 1279
Security: See also Federal Security Agency Security Act, New Zealand, administration, 1093
Security Act, U. S., (amendments) 147-OS;
1904-OS; (allocation of federal funds to states) [Leland] *1084; (A. M. A. not liable for taxes under) 1894-OS
Security Act, U. S. National Health Program; See under Health
Security, American Association for, 1361-E
Security Department, (appointments, Minn.) 594

Society of Clinical Surgery, 1091; 1469
state and county, efficiency; constitutions and by-laws, 1888-OS
state and county, graduate work on industrial health, (Council statement) *586
state and county, medical service plans, 55
state and county, members not licensed in respective states, [West] 166-ab
state, Annual Conference of Secretaries, 55
state, committees on industrial health, (Council statement) *581
state, condemn patents for profit, Ala., 2313
state, medical journals, [Kopetzky] *256;
state, organization, 1887-OS
state, public relations committee, [Fishbein] 228-ab; [Barker] 239-ab
SODASAL, 2585-BI
SODIUM acetate and theobromine, N. N. R. (Mallinckrodt) 961
Amystal: See Anesthesia
benzoate, caffeine with, (Upjohn) 2387; (Lake-Laboratories) 2387
Bicarbonate Treatment: See Diabetes Mellitus coma
Bromide: See Epilepsy Treatment
cacodylate N. N. R. (Upjohn) 1557; (Maltbie) 1883
Chloride: See also Salt
chloride enema in intestinal paralysis, [Stephens] 1015-ab
chloride excretion and adrenocortical function, 551
chloride infection, neurosis also blood pressure and pulse after, [Krause & Sherman] *813
chloride treatment of dehydration, acidosis and alkalosis, [Darrow] *555
chloride (dihydrate) for preserving blood [Darrow] 520-ab
chloride, first transfusion with, 816; [Lewisohn] 1: See Dilantin; Epilepsy treatment

- SODIUM**—continued
fluoride, food poisoning from, 671
formaldehyde sulfoxylate for mercury bichloride poisoning, [Monte & Hull] *1433
formaldehyde sulfoxylate, relation to iron and ascorbic acid metabolism, [Moore] 440—ab
hexametaphosphate, dissolving kidney stones with, 275
hypochlorite, footbath solutions for ringworm, 1577
in Blood: See Blood
Iodide: See Sciatric treatment
Morrhuate with Quinine, N. N. R., 1156
Nitrite: See also Cyanide poisoning
nitrite collapse, effect of paredrinol on, [Kunkel] 190—ab
nucleinate, effect on leukocytosis, [Norden-son] 197—ab
diPhenyl hydantoinate: See Dilantin; Epilepsy treatment
p,p'-diaminodiphenylsulfone- N,N'-di-dextrose sulfonate (promin), [Johnson] 520—ab
Sallylate: See Sciatric, treatment
Sulfanilyl Sulfanilamide: See Sulfanilamide and Derivatives
Sulfapyridine: See Sulfapyridine
sulfate cathartics, sulfanilamide and sulfapyridine incompatible with, 1393
Sulfate Treatment: See Wounds, infected
Tellurite Test: See Diphtheria diagnosis
thiosulfate for conserving blood, [Corelli] 2262—ab
Thiosulfate, Gold: See Arthritis, treatment; Gold
SODOKU: See Rat-Bite Fever
SOLDIERS: See also Army; European War; Military Service; Russo-Finnish War; Veterans; etc.
Identification tag contains blood group record, (Germany) 675; (Australia) 1092
SOLUTIONS: See Dextrose; Sugar; Sulfanilamide and Derivatives; etc.
SOLVENT: See Stoddard's Solvent
SOMATIC Complaints: See Psychosomatic Medicine
SOPORIFICS: See Sleep disorders
SOUP, Beech-Nut Brand, 661; 871
SOUR, neutralizing, use in laundries, 1286

SUBJECT INDEX

Jour. A. M. A.
June 29, 1940

- VENEREAL DISEASES**—Continued
control in European War, 206; [Ormond]
1826—C
control program, A. M. A. resolutions on,
2477. OS
control standards of U. S. Public Health
Service, 423
courses in, New York, 2228
International Union Against, resolutions and
recommendations, 476
prevention, Argentina, 1822
prevention, condoms, A.M.A. Council's report
on, 2116
state laws on, [McDavid] 877 OS; (pro-
phylaxis) 878 OS; (prenatal examina-
tion) 1906—OS
transmission, no danger in swimming pool,
2049
- VENISECTION**, hemophilia treated by, [Law-
son & Graybill] *2299
- VENOM**: See Cobra; Pain, relief of; Snake
Carrier Room Ventilator, Type 50R, 703
- VENTRICULIN**: See Stomach Inflammation
- VERHOEFF**, F. H., *Archives of Ophthalmology*
to honor, 898—OS
- VERTIGER**: See Spine
- VERTIGO**, Ménière's, [Clop] 529—ab
aural, Ménière's syndrome, Furstenberg diet
in, 1828
aural, Ménière's syndrome, histologic changes,
[Hallpike] 625—ab
aural, Ménière's syndrome, low salt diet with
and without ammonium chloride or potas-
sium sulfate vs. acoustic nerve surgery,
[Walsh & Adson] *130
aural, Ménière's syndrome, potassium chloride
cause of weakness and dizziness, 2404
- VETERANS** Administration activities, 473
legislation, bills pending, 153 OS
medical care and other benefits, federal laws
enacted, 149—OS
Medical Council, new members, 802
- VICTORIAN** Bush Nursing Association, report,
Australia, 1386
- VIGOR** Tablata (El Spano) 75—B
- VINEGAR** Water Douche: See Trichomonas
- VINETHYLENE** Anesthesia: See Anesthesia,
vinyl ether
- VINSON-Plummer** Syndrome: See Plummer
Vinson Syndrome
- VIOFORM**: See Trichomonas Infection
- VIOSTEROL**, L.V.C. Halbut Liver Oil with,
1356
- VIRCHOW**, RUDOLF, microscope selected by,
1722—SS
- VIRGINIA**, University of: See University
- VIRILISM**, adrenal cancer causes, [McGavack]
1901—ab
androgen therapy causes, [Gold & others]
*1541
- VIRUS**: See also Euccephalomyelitis; Polio-
myelitis
architecture, 328—E
(also books on viruses) 1578
diseases and, 1558—E
diseases, infection and immunity in, 1885—E
diseases, sulfanilamide for, [Burr] 2156 ab
filterable, atypical bronchopneumonia caused
by, [Murray] 2337—ab
filterable, tumors caused by, 2317
620
filterable, virulence in frozen state, [Turner]
1722—SS
- VISCERA**, abdominal, distention effect on cor-
onary circulation, [Gibber] 610 ab
transposition with biliary disease, [Wood]
2417 ab
- VISION**: See also Eyes; Glasses; Ophthal-
mology
acuity, aphakia: percentage of visual loss
after cataract extraction, 1480
color: See Color Blindness
conservation, A. M. A. resolutions on, 1894
OS; 2476 OS; 2509 OS
Dark Adaptation, slight saving in Tasmania, 1387
Defective: See Eyes accommodation
disability from colored paper, 2323
disorders after sulfanilamide, [Hughes] 514
during flight, 306 ab
loss of: See also Blindness
loss of, estimating disability, [Grady] 989
loss of (gradual), central choroiditis due
to streptococcal infection? 1480
testing, results obtained by ophthalmologist
vs. optometrist, 416 E
testing school children with Betta telephoto-
lar machine, Snellen charts or Lancaster
tests, 1090; (reply) [Burroughs] 2051
- VISOR** to prevent war injuries to eye, 2307
- VITAL PRODUCTIONS** Company fraud, 75—B
- VITAL STATISTICS**, birth rate increased, Ger-
many, 60
birth rate (low), France, 339
birth rate, relation to postwar tuberculosis
mortality, [Wolff] 282—ab
births, 1940 census data, 1270 E
births, ratio of, to graduates in cities having
medical schools, 146 OS
- VITAL STATISTICS**—Continued
death rates of gainfully occupied males,
Council statement, *574
Mortality: See also Cancer; Diphtheria; In-
fant, mortality; Material; Tuberculosis;
Vital Statistics death rate; etc.
mortality in hospitals by states, *1171; *1172
mortality trends since 1916, U. S., 422
of England, 206; 2049
of Germany, 252 E
of Italy, 1387
of New York City, 203
registration (continuous) recommended for
U. S., 330—E
- VITALLIUM** Treatment: See Fractures
[Tuohy] *223
containing alcoholic beverages, labeling of,
1671—E; [Newell] 2480—C
deficiency, adenylic acid for, [Spies] 2334—ab
deficiency affects other diseases, [Yonmans]
694 ab
economy and sympathetic endocrine system,
[Stepp] 2513—ab
hormones relation to [Eller & Wolff] *2002
in avocado and avocado oil, 432
in cosmetics: absorption by skin, [Eller &
Wolff] *1805; *2002
in human milk sufficient for newborn baby?
1287
lectures on, New York, 1408
of respiratory ferment system in anemia,
[Gibber] 65 ab
patents to provide chemistry fellowships, 2175
regulations by Food and Drug Administration,
1559 E; (hearings revoked) 1082
requirements of industrial worker, [Bocher]
*552
research prize (\$1,000) awarded by Mead
Johnson & Co., 2132
topical application, [Eller & Wolff] *2005
treatment plus gold in arthritis, [Secher]
2512 ab
tumor development and, [Eller & Wolff]
*2007
- VITAMINS A**: See also Carotene; Cod Liver
Oil
absorption in catarrhal jaundice, [Breese]
1592 ab
cancer from topical application, 1008
Dark Adaptation and: See Vitamin A def-
iciency
deficiency, dark adaptation in infants, [Lewis]
690—ab
deficiency, anthrax from, [Corden] 615
deficiency, biophotometer test an index,
[Thomson] 195—ab; [Steininger] 526—ab;
[Baum] 2410—ab
deficiency, cystic pancreatic fibrosis and bron-
chectasis, [Anderson] 690—ab
deficiency, dark adaptation an test, [Harris]
1023 ab; (in liver diseases) [Wolff] 1592
ab
deficiency, dark adaptation in, effect of
anoxemia on, [McDonald] 616 ab
deficiency in America, [Lehman & Rapaport]
*392
deficiency in children on emergency relief,
skin signs, [Lehman & Rapaport] *386
deficiency in diabetes, [Hrazer] 922 ab
doses (excessive), systemic effects from,
[Eller & Wolff] *2001
in blood (corrected), 337
in cooked peas and spinach, [Bocher] 281
in market milks, [Dornbush & others] *1748
in quick frozen fruits and vegetables, [Rose]
*1350
requirements, [Lehman & Rapaport] *391
topical application, [Eller & Wolff] *2005
treatment of typhoid in children, [Graud]
832 ab
- VITAMINS B COMPLEX** deficiency in trench
foot, 1471
deficiency, nervous disturbances from, et-
iology role of arsenic, [Scott] 1112—ab
deficiency, nutritional disorders from, [Abram]
2401 ab
treatment of alcoholic diseases, [Ansey] 283
treatment of digestive disturbances, [Chesley]
1013 ab
treatment of nerve deafness, [Veney] 1017
treatment of neuritis symptoms, [Stone]
*2190
tumors not produced with, [Ginzton] 1407
B₁: See also Acid, nicotinic; Thiamine
chloride
B₁ deficiency, cutaneous changes in, 509
B₁ deficiency encephalopathy, [Joffe &
others] *307
B₁ deficiency, Parkinson's syndrome not re-
lated to, 1100
B₁ deficiency, treatment of dropsy, [Marvin]
*702
B₁, effect on morphine abstinence symptoms,
[Fitzhugh] 830 ab
B₁ in quick frozen fruits and vegetables,
[Rosa] *1350
- VITAMINS B COMPLEX**—Continued
B₁ metabolism, thiamine excretion diagnostic
value in, [Robinson] 438—ab
B₁ need for adding to staple American foods;
change milling practice, [Marks] 512—C
B₁ requirement of navy, 475
B₁ role in delirium tremens, [Klene & others]
*2191
B₁ (thiamine, Betaxin), use for relief of pain
in varicose ulcers, [Ochaner & Smith] *917
B₁ tolerance tests, [Molnar] 2602—ab
B₁ treatment of multiple sclerosis, (Stern's)
181; [Moore] 921—ab
B₁ treatment of neuro-anemic syndrome,
[Schelouff] 1009 ab
B₁ treatment of otosclerosis, [Haer] 1069
—ab
B₁ treatment of pain from tonsillectomy,
[Haer] 1001—ab
B₁ treatment of painful amputated stumps,
[Hilshberg] 930—ab
B₁ treatment of pink disease, [Forryth] 361
—ab
B₁ treatment of radiation sickness, [Imier]
1958 ab
B₁ treatment of trigeminal neuralgia, (Hor-
nook & others) *1421; (correction) 1042
B₂: See also Riboflavin
B₂ deficiency: See Riboflavin
B₂ in quick frozen fruits and vegetables,
[Rose] *1350
B₂, pyridoxine term for, Council report, 2387
dystrophy, [Antopol & Schotland] *1058
VITAMIN C: See also Acid, ascorbic; Scurvy
deficiency in normal adult, [Crandon] 2599
ab
deficiency in surgical patient, [Wolfer] 448
deficiency, osteopathia due to, 675
diet (low), alcaptonuria produced by, 1069
effect on renal threshold of blood sugar,
[Ritter] 2314—ab
in blood during and after pregnancy, [Sa-
dovsky] 101—ab
in blood of Chinese, [Yu] 929—ab
in fruit juices, effect of kitchen procedures,
[Ingalls] 89—ab
in quick frozen fruits and vegetables, [Rose]
*1350
metabolism and ultraviolet irradiation, [Jun-
geblut] 527—ab
metabolism, relation to iron, [Moore] 440
—ab
prevention of leukopenia in x-ray irradiation,
[Carrié] 199—ab
prothrombin time not related to, [Kark] 531
—ab
requirement of navy, 475
topical application, [Eller & Wolff] *2005
treatment of diphtheria, typhoid and pneumo-
nia, [Schmidt] 2200 ab
treatment of granulocytopenia, [Kalk] 700
—ab
treatment of hemorrhagic diatheses, [Armen-
iano] 2008 ab
treatment of hemorrhagic purpura with gran-
ulocyte reactions, [Gottel] 2343—ab
2001—ab
treatment of otosclerosis, [Haer] 1069—ab
treatment of posttonsillectomy pain, [Haer]
1001 ab
VITAMINS D: See also Cod Liver Oil; Halbut
Liver Oil; Vitamin
complex in progressive myopia, [Knapp] 615
doses (excessive), systemic effects from, [Eller
& Wolff] *2004
resistant rickets, [Gill] 360—ab
topical application, [Eller & Wolff] *2005
treatment of rickets, cancer from? 1008
one massive dose, [Vollmer] 2419—ab
—ab
treatment of skin disease, [Maynard] 2591
- VITAMINS E**, rancidity destroys, 1742—ab
stability in wheat germ oil, [Clausen] *2217
treatment of amyotrophic lateral sclerosis
with (cephaloid), [Hicknell] 1120 ab;
[Wechsler] *918
treatment of habitual abortion, sterility, de-
layed menstruation, toxemia of pregnancy,
faulty lactation and vaginal puritus with
wheat germ oil, (Council report), [Clausen]
*2214
treatment of muscular dystrophies, etc., with
wheat germ oil, [Stone] *2187
treatment of muscular dystrophies, tuber dor-
salis, myopathies, etc., [Hicknell] 1120—ab
treatment of threatened or habitual abortion
with wheat germ oil, [Collins] 2310—ab
tumors not produced with, [Ginzton] 1407
—ab
- VITAMINS F** in cosmetic preparations, [Eller
& Wolff] *2003
- VITAMINS G**: See Vitamin B₂
- VITAMINS K**, absorption of, and decelerated
deficiency, prothrombin in blood of infants,
[Kato & Poncher] *719
hepatectomy, plasma prothrombin and, [An-
drus] 623—ab
lacking in infants, [Dam] 531—ab

VITAMINS K—Continued
nutritional deficiency, [Kark] 531—ab
role in hemorrhage of newborn, [Waddell] 696—ab; [Quick] 1014—ab
synthetic, 2-methyl-1, 4-naphthoquinone for prothrombin deficiency, [Rhoads & Fliegelman] *400; [Sharp] 439—ab; [Quick] 440—ab; [Andrus & Lord] *1336
synthetic; 2-methyl-1:4-naphthoquinone in obstructive jaundice, [Macfie] 831—ab
treatment of hemophilia, 1479
treatment of hepatic or biliary tract disease, [Pohle] 1962—ab
X, synthetic (2-methyl-3-phytyl-1, 4-naphthoquinone) in hypoprothrombinemia

K: naphthol hydro-

VITAMINS P, 43—E
VIVISECTION: See Animal Experimentation
VOCATIONAL rehabilitation, [Foster] 889—ab
